Study description

Previous research suggests that people who are overweight or obese may have a higher risk of developing Parkinson’s disease than people with normal weight, while other studies show no such association. The objective of this study is therefore to investigate the association between BMI and risk of Parkinson’s disease. A cohort will be derived from CPRD of people aged 40 years or older with a first BMI recording between 1992 and 2007. People with a prior record of Parkinson’s disease or dementia will be excluded. Incidence rates of Parkinson’s disease will be calculated for each BMI category using Poisson regression, adjusting for differences in patient characteristics and allowing for competing risks with a novel approach. This study will provide information from a very large number of people (2 million) with a sizeable amount of follow-up data in a representative sample. The findings will therefore provide important information to help clarify the relationship between BMI and Parkinson’s disease to inform preventative and therapeutic strategies for Parkinson’s disease.

Methodological aspects

Study type

Study type list

Study type:

Non-interventional study

Scope of the study:

Assessment of risk minimisation measure implementation or effectiveness

Disease epidemiology

Main study objective:

The primary objective is to estimate the age-specific associations between BMI and Parkinson’s disease.Secondary objectives are to assess the shape of the association and Identify potential modifiers and confounders of the risk.The results will be usable for disease prediction models, patient management, the planning of trials, and help in hypotheses of pathophysiological mechanisms of PD

Study Design

Non-interventional study design

Cohort

Study drug and medical condition

Medical condition to be studied

Obesity

Parkinson's disease

Population studied

Short description of the study population

2 million patients followed up over 2 decades. Underweight (< 20 kg/m2): 106,716 people Healthy weight (20-24.9 kg/m2):629,126 people Overweight (25-29.9 kg/m2): 727,339 people Obese (≥ 30 kg/m2): 489,406 people With a median follow-up of 9·3 years, PD occurred in 11,616 people.

Age groups

Adults (46 to < 65 years)

Adults (65 to < 75 years)

Adults (75 to < 85 years)

Adults (85 years and over)

Estimated number of subjects

2000000

Study design details

Outcomes

Parkinson´s disease

Data analysis plan

We compared rates of PD across categories of BMI using Poisson regression models. Standardised incidence rates and rate ratios were either adjusted for age (in five-year bands) and sex, or further adjusted for the following covariates, measured at the time of index BMI. We used age at diagnosis, updating the data as people moved through the age categories during follow-up. Incidence rates were standardised to the age and sex distribution of the overall study population. We performed analyses to investigate whether the association between BMI and PD varied depending on the time from the index BMI measurement. We calculated the cumulative incidence of PD using the Kaplan-Meier estimator, with age as the underlying time scale.We performed a sensitivity analysis to investigate whether our findings could be reasonably explained by competing risks usinga novel approach under a hypothetical scenario and using matching
