Study description

This retrospective database study aims to understand characteristics of Idiopathic Pulmonary Fibrosis (IPF) patients treated with nintedanib and pirfenidone, as well as patients who do not receive a prescription for an antifibrotic treatment. The primary objective is to describe and compare demographic, clinical, and other characteristics of IPF patients initiating nintedanib, pirfenidone, or not receiving prescription antifibrotic treatment. The secondary objective is to compare and contrast the probability of receiving nintedanib vs. pirfenidone and nintedanib or pirfenidone vs. untreated in IPF patients using baseline patient characteristics.

Was the study required by a regulatory body?

No

Is the study required by a Risk Management Plan (RMP)?

Not applicable

Methodological aspects

Study type

Study type list

Study topic:

Disease /health condition

Study type:

Non-interventional study

Scope of the study:

Drug utilisation

Data collection methods:

Secondary use of data

Main study objective:

To understand characteristics of IPF patients treated with nintedanib and pirfenidone, as well as patients who do not receive a prescription for an antifibrotic treatment in the United States

Study Design

Non-interventional study design

Cohort

Study drug and medical condition

Medical condition to be studied

Idiopathic pulmonary fibrosis

Population studied

Short description of the study population

US population receiving healthcare in the ambulatory setting. Patients were included in one of three study cohorts based on prescription history from October 1, 2014 to April 30, 2018, allowing for a 12-month preindex period to describe patient demographic, clinical and treatment characteristics.

Age groups

Adults (46 to < 65 years) Adults (65 to < 75 years) Adults (75 to < 85 years) Adults (85 years and over)

Special population of interest

Hepatic impaired Immunocompromised Pregnant women Renal impaired

Estimated number of subjects

13300

Study design details

Outcomes

The primary outcome will be the ASD and p-value comparing baseline patient characteristics between patients treated with nintedanib vs. pirfenidone, nintedanib vs. untreated and pirfenidone vs. untreated, The secondary outcomes are the adjusted odds ratios of receiving one treatment over another (or probability of receiving antifibrotic treatment) between the following cohorts:• Nintedanib vs. pirfenidone• Treated patients (i.e. nintedanib or pirfenidone) vs. untreated

Data analysis plan

For the primary objective, baseline patient characteristics will be described using descriptive analysis, i.e. described as counts and percentages for categorical variables and measures of central tendency (mean, median, SD, and min/max) for continuous variables. Differences between the cohorts will be assessed using ASD, where an ASD of at least 10% will be considered a meaningful difference. Patients with missing data will be reported as missing and excluded from the comparison for the missing variable. Bivariate statistical significance tests such as Chi-square test for categorical variables and Wilcoxon rank sum test or t-test for continuous variables (depending on distribution of data) will be performed to compare differences in baseline characteristics between the three cohorts. In addition to standardized differences, p-values will be reported. A multi-variable logistic regression model will be constructed for the secondary objective.
