Study description

CAESAR is an Italian multicenter retrospective cohort study on Rare Neuromuscular and Neurodegenerative diseases (RND), based on information available in regional administrative healthcare databases. The aims are 1) to describe the prescriptive patterns of drugs used for the treatment of patients affected by RND and identify patient characteristics associated to these patterns in the three Italian regions (Tuscany, Umbria, Lazio), accounting for over 10 million residents, and 2) to perform a comparative evaluation of the effectiveness and safety of drugs used for the treatment of RND, with a focus on specific active agents. The study population will be enrolled in the period 2009-2019, with a two-year look-back and at least 1 year of follow-up, including patients, resident in one of the three regions and affected by Amyotrophic lateral sclerosis (ALS), Progressive muscular atrophy (PMA), Pseudobulbar palsy, Progressive bulbar palsy (PBP), Primary lateral sclerosis (PLS), Other motor neuron disease, Myasthenia gravis (MG). Patients will be defined from Hospital discharge records (ICD-9-CM codes), disease specific copayment exemptions, and, as far as possible, disease specific drug treatments. Drug utilisation patterns will be based on drugs (ATC codes) prescribed to outpatients using the DDDs. Safety and effectiveness will be investigated using a new-user approach and applying both, intention-to-treat and as-treated analysis. Clinical data available in two of the participating regions for ALS patients will be used to 1) validate the algorithm used for patient identification, 2) validate the exposure definition, and 3) perform external adjustment. Data and analysis ill be managed through a common data model, with shared data scripts, performing the analysis at regional level (in-house) and pooling aggregated anonymous data to obtain overall results.

Methodological aspects

Study type

Study type list

Study type:

Non-interventional study

Scope of the study:

Drug utilisation

Effectiveness study (incl. comparative)

Main study objective:

Objective 1. describe the prescriptive patterns of the study drugs in patients affected by RND and identify patient characteristics associated to these patterns in the three Italian regions (Tuscany, Umbria, Lazio), accounting for over 10 million residents. Objective 2. comparative evaluation of the effectiveness and safety of drugs used for the treatment of RND, with a focus on specific agents

Study Design

Non-interventional study design

Cohort

Study drug and medical condition

Medical condition to be studied

Amyotrophic lateral sclerosis

Progressive muscular atrophy

Pseudobulbar palsy

Progressive bulbar palsy

Upper motor neurone lesion

Motor neurone disease

Myasthenia gravis

Additional medical condition(s)

Other RNDs might be included during the study

Population studied

Age groups

Term newborn infants (0 – 27 days)

Infants and toddlers (28 days – 23 months)

Children (2 to < 12 years)

Adolescents (12 to < 18 years)

Adults (18 to < 46 years)

Adults (46 to < 65 years)

Adults (65 to < 75 years)

Adults (75 to < 85 years)

Adults (85 years and over)

Estimated number of subjects

5000

Study design details

Outcomes

Overall and cause specific mortality, Admission to intensive care unit, Remission from corticosteroid use, discontinuation after a period of prescriptions with corticosteroids for systemic use, Adverse drug reactions (serious infections, autoimmune disease) - to be defined, Respiratory failure and tracheotomy (for ALS patients), Thymoma, thymectomy, myasthenia gravis crisis, use of intravenous immunoglobulins, plasmapheresis (for MG patients)

Data analysis plan

Data will be organised and managed through a common data model. Analysis will be performed running the shared scripts at local level and pooling aggregated data at the end. Drug utilization will be defined on the basis of DDDs, using different indicators: prevalence of use (by dividing the number of

drug users by the overall resident population), prevalence of use among patients in the cohort (by disease for single drugs), DDDs per 1000 users per day (the mean number of doses consumed every day by 1000 patients included in the cohort). CER will be performed through a propensity matched cohort design (head-to-head comparison between different drug groups/drugs). Patients in the compared exposure groups will be propensity matched. A group of patients not treated with any of the drugs will also be defined and compared. Intention-to-treat and As-treated analyses will be performed using Cox proportional Hazard models (HRs and 95%CIs).

Data management

ENCePP Seal

The use of the ENCePP Seal has been discontinued since February 2025. The ENCePP Seal fields are retained in the display mode for transparency but are no longer maintained.
