Study description

Establishing modifiable risk factors of dementia risk is a global priority. The relationship of lipids to the risk of developing dementia is unclear. Previous research based on small studies suggests that people who have high cholesterol in midlife may have an increased risk of developing dementia some 20 years later. The proposed study will use information from a large number of people in the UK to investigate the relationship between lipids (total cholesterol, LDL and HDL) and the future risk of developing dementia. People aged 40 years or older with a lipid reading between 1992 and 2009 will be selected from the CPRD primary care database. Their recorded development of dementia will be investigated, whilst accounting for differences in characteristics (e.g. age, gender, etc.). This study will provide information from a very large number of people with a sizeable amount of follow-up data which will be representative of the UK population. The findings will therefore provide important information to help clarify the relationship between lipids and dementia. The findings will help to inform preventative strategies for dementia.

Was the study required by a regulatory body?

No

Is the study required by a Risk Management Plan (RMP)?

Not applicable

Methodological aspects

Study type

Study type list

Study type:

Non-interventional study

Scope of the study:

Assessment of risk minimisation measure implementation or effectiveness

Disease epidemiology

Main study objective:

The primary objectives of the analysis is to estimate the age-specific association between lipids - total cholesterol, low density lipoprotein (LDL) and high density cholesterol (HDL) and future risk of Alzheimer´disease, vascular

dementia and all dementia.

Study Design

Non-interventional study design

Cohort

Study drug and medical condition

Medical condition to be studied

Lipids

Dementia Alzheimer's type

Vascular dementia

Hyperlipidaemia

Hypercholesterolaemia

Population studied

Age groups

Adults (46 to < 65 years)

Adults (65 to < 75 years)

Adults (75 to < 85 years)

Adults (85 years and over)

Estimated number of subjects

1800000

Study design details

Outcomes

Alzheimer´s disease, Vascular dementia, All dementia, All-cause death

Data analysis plan

To relate lipids (total choleterol, LDL and HDL) to risk of dementia, Poisson regression models will be used to estimate incidence rates and rate ratios. Adjustment for age (in 5-year bands), sex, and baseline date (at index). To update age at risk as people move through the age categories. Adjustment of rate ratios for additional baseline cardiovascular covariates. To fit separate Poisson regression models in each category for follow intervals and age-at-risk. Correction for regression dilution bias using serial lipid measurements. To assess selective mortality bias, a simulation study to investigate the size of competing risk of mortality, with ´joint frailty´ models. To confirm well-established association of lipids with all cause mortality
