Study description

This NIS will investigate changes in dyspnea or cough as measured with the L-PF questionnaire over 52 weeks of nintedanib treatment in patients suffering from chronic fibrosing ILD with a progressive phenotype (excluding IPF), including a snapshot-analysis before last patient in (LPI) to evaluate a possible correlation between changes in FVC and L-PF (dyspnea and cough). The study hypothezises that in a one year observational study a correlation can be found between changes in lung function measured by FVC and the changes in the scores for dyspnea and cough of the L-PF questionnaire in ILD patients. 100 patients will be included in 20 sites in Germany.

Methodological aspects

Study type

Study type list

Study topic:

Human medicinal product

Study type:

Non-interventional study

Scope of the study:

Drug utilisation

Effectiveness study (incl. comparative)

Data collection methods:

Primary data collection

Study design:

Single-arm, open-label observational cohort study according to §4, section 23 and §67, section 6 German Medicines Act

Main study objective:

The primary objective is to investigate changes in dyspnea or cough as measured with the L-PF questionnaire over 52 weeks of nintedanib treatment in patients suffering from chronic fibrosing ILD with a progressive phenotype (excluding IPF), including a snapshot-analysis before LPI, to evaluate a possible correlation between changes in FVC and L-PF (dyspnea and cough).

Population studied

Short description of the study population

patients suffering from chronic fibrosing ILD with a progressive phenotype

Age groups

- Adults (18 to < 46 years)
- Adults (46 to < 65 years)
- Adults (65 to < 75 years)
- Adults (75 to < 85 years)
- Adults (85 years and over)

Estimated number of subjects

100

Study design details

Setting

Data of 100 patients suffering from chronic fibrosing ILD with a progressive phenotype treated with nintedanib in routine suffering from chronic fibrosing ILD with a progressive phenotype practice are planned to be recruited for this NIS by about 20 specialists, experienced in treating ILD patients, (e. g., pulmonologists and rheumatologists) throughout Germany.

Outcomes

Correlation between change from baseline to week 52 in FVC % pred. and change from baseline to week 52 in dyspnea symptom score Correlation between change from baseline to week 52 in FVC % pred. and change from baseline to week 52 in cough symptom score, Correlation between change from baseline to week 52 in FVC mL and change from baseline to week 52 in dyspnea symptom score Correlation between change from baseline to week 52 in FVC mL and change from baseline to week 52 in cough symptom score Absolute change from baseline in L-PF cough symptom score at week 52 Absolute change from baseline in L-PF dyspnea symptom score at week 52

Data analysis plan

All patients having received at least one dose of nintedanib will be included in the treated set. All analyses will be performed on the treated set. For the analysis of the primary and secondary outcomes related to correlations, Pearson measures of correlation along with 95% two-sided confidence intervals and the two-sided p-values will be provided. The secondary outcomes related to absolute changes will be analysed using a restricted maximum likelihood (REML) based repeated measures approach. Analyses will include the fixed, categorical effect of visit, as well as the continuous, fixed covariates of baseline and baseline-by-visit interaction. An unstructured (co)variance structure will be used to model the within-patient measurements. Time to event endpoints over the whole trial will be analysed in a descriptive manner. Frequency tables and

Kaplan-Meier plots will be produced. Further continuous and categorical outcomes will be analyzed descriptively. No subgroup analyses are planned.

Summary results

Study population (102 treated patiens (pts.): mean age 70.47 ± 10.74 years, males (62.75%). Race/ethnicity not collected. Former (45.10%) or current (3.92%) smokers. Diagnoses: autoimmune disease associated ILDs (44.12%), IIPs (32.35%), exposure related ILDs (19.61%), sarcoidosis (3.92%).
Baseline mean FVC was 65.18 ± 18.86% pred. and 2296.37 ± 769.77 ml. After 52 weeks of nintedanib treatment, mean FVC was 65.67 ± 19.62% pred. and 2304.79 ± 710.73 ml. Mean dyspnea symptom score was 24.71 ± 18.56 at baseline and after 52 weeks of treatment, the score was 27.32 ± 21.67. Mean cough symptom score was 37.46 ± 25.67 at baseline and 36.85 ± 28.59 after 52 weeks of treatment.
Due to missing patient questionnaires or other necessary variables for 64 out of all 102 patients, the primary outcome was analyzed for a total of 38 patients.
For the primary outcome, the correlation between change in FVC [% pred.] and change in dyspnea symptom score, the Pearson correlation coefficient was -0.26 and the p-value was 0.12 (95% CI -0.53 to 0.07). For the correlation between change in FVC [% predicted] and change in cough symptom score, the Pearson correlation coefficient was -0.11 and the p-value was 0.51 (95% CI -0.41 to 0.22).
For the secondary outcome, the correlation between the change in FVC [ml] and change in dyspnea symptom score, the Pearson correlation coefficient was -0.29 and the p-value was 0.08 (95% CI -0.56 to 0.03). For the correlation between change in FVC [ml] and change in cough symptom score, the Pearson correlation coefficient was -0.16 and the p-value was 0.35 (95% CI -0.45 to 0.17). Absolute change in dyspnea symptom score from baseline to week 52 was 6.75 ± 18.51, and in cough symptom score it was 2.50 ± 24.04.
69 pts. (67.65%) experienced 139 TEAEs. Overall, 24 STEAEs were reported in

16 pts. (15.69%), 91 TEADRs in 53 patients (51.96%), 3 STEADRs in 3 patients (2.94%), and 4 TEASIs in 3 pts. (2.94%). There were 10 fatal STEAEs among 8 pts. (7.84%).
