Study description

Empagliflozin (Jardiance), a highly potent and selective inhibitor of the sodium-glucose cotransporter 2 (SGLT2), was approved in Europe in May 2014 for the treatment of type 2 diabetes mellitus (T2DM) to improve glycaemic control in adults. As part of the risk management plan, Boehringer Ingelheim International GmbH (BI) has committed to conduct a post-authorisation safety study (PASS) to evaluate the liver and renal safety of empagliflozin. The study will also evaluate the risks of severe complications of urinary tract infections (UTIs), genital infections and diabetic ketoacidosis. To evaluate the association between empagliflozin use and mentioned outcomes routinely collected health information from the Clinical Practice Research Datalink (CPRD), in the United Kingdom. For the evaluation of the rarest outcomes, the Danish Population Registries in Denmark and the HealthCore Integrated Research Database (HIRD) in the United States. This PASS will be conducted through an observational cohort study among adult patients with T2DM and at least 12 months of continuous enrolment in the data source where new users of empagliflozin will be compared to new users of dipeptidyl peptidase-4 (DPP4) inhibitors. Estimations will be made on the crude and adjusted incidence rates and adjusted incidence rate ratios of the primary and secondary outcomes. The primary outcomes will be: acute liver injury (ALI) in patients without predisposing conditions, acute kidney injury, severe complications of urinary tract infection, genital infections, and diabetic ketoacidosis. The secondary

outcomes will be: ALI in patients with or without predisposing conditions, chronic kidney disease, and severe genital infections.

Study topic:

Disease /health condition

Human medicinal product

Study type:

Non-interventional study

Scope of the study:

Assessment of risk minimisation measure implementation or effectiveness

Safety study (incl. comparative)

Data collection methods:

Secondary use of data

Main study objective:

To estimate, among patients with type 2 diabetes mellitus, the risk of acute liver injury, acute kidney injury and chronic kidney disease, severe complications of urinary tract infections, genital infections and diabetic ketoacidosis among patients treated with empagliflozin compared with patients treated with dipeptidyl peptidase-4 inhibitors.

Population studied

Short description of the study population

Patients aged 18 years or older diagnosed with type 2 diabetes received treatment with empagliflozin or DPP-4 inhibitor identified from the Clinical Practice Research Datalink (CPRD) database for the study period of August 2014 to August 2019.

Inclusion criteria:

· Be aged 18 or more years at the index date.

· Have at least 12 months of continuous registration before or at the index date. In the CPRD this means registration in a primary care practice with up-to-standard data. In Denmark, this means residency in the country. In the HIRD, this means enrolment in the health care plan.

· Have T2D ever before or at the index date: the algorithm to identify patients with T2D will be adapted to the type of data available in each data source. This algorithm may include medication codes and will be described in the statistical epidemiological analysis plan.

Exclusion criteria:

· Patients with a confirmed diagnosis of T1D before or at the index date will be excluded from the study.

· Patients prescribed/dispensed combinations of SGLT2 inhibitors with DPP-4 inhibitors at the index date (as fixed-dose combinations such as Glyxambi® [empagliflozin and linagliptin], or as non–fixed-dose combinations of the two individual medications prescribed on the same date) will be excluded.

Age groups

- Adults (18 to < 46 years)
- Adults (46 to < 65 years)
- Adults (65 to < 75 years)
- Adults (75 to < 85 years)
- Adults (85 years and over)

Special population of interest

Special population of interest, other

Type 2 diabetes mellitus patients

Estimated number of subjects

151184

Study design details

Outcomes

Acute liver injury, acute kidney injury, severe complications of urinary tract infection, genital infections, diabetic Ketoacidosis, acute liver injury in a subset of patients with or without predisposing factors, chronic kidney disease, severe genital infections

Data analysis plan

The following estimates and comparisons will be generated: Crude and adjusted incidence rates of each of the outcomes among empagliflozin new users and DPP-4 inhibitor new users. Incidence rates will be reported as point estimates (in cases per 1,000 person-years) and 95% confidence intervals (CIs). Summary IRRs, after adjusting for propensity score deciles, among empagliflozin new users vs. DPP-4 inhibitor new users. The adjusted IRRs for each of the primary outcomes will be the main effect estimates of interest. Adjusted incidence rates and IRRs will be calculated using analytic techniques involving stratification by categories of propensity scores. An additional analysis will further stratify the IRRs by categories of insulin use at the index date. Sensitivity analyses will be performed to evaluate the potential for other sources of bias and confounding. Meta-analytic methods will be used to combine the IRRs obtained from the main analysis performed by all the data sources.
