INVESTIGATION OF PSYCHIATRIC ADVERSE EVENTS FOLLOWING EXPOSURE TO LEVONORGESTREL CONTAINING INTRAUTERINE DEVICES

Data analysis plan of THIN electronic health record data

Roles

Lead investigators	Jim Slattery and Daniel Morales
Data analysis	Jim Slattery
Peer review	Luis Pinheiro
Sign-off	Xavier Kurz

Study aim

This study investigates whether levonorgestrel delivered by an intra-uterine device (LNG IUD) increases the risk of anxiety, panic attacks, sleep disorders and restlessness.

Data source

UK electronic primary care data contained within the THIN database.

Study design and selection criteria

Given the long term nature of the IUD exposure, a cohort study with time to first occurrence of a diagnosis related to the events of interest following insertion of the IUD will be conducted. A control arm consisting of women using IUDs not medicated with levonorgestrel (or other hormonal product) will provide a comparison. Age, factors associated with the outcome events and differences in indications between the LNG medicated and un-medicated IUDs will be taken into account. Matching on practice may help to balance some unknown social factors.

Eligible participants for the active arm of the study will include women fitted with an LNG IUD and with more than one year of prior data collection in THIN. A search over time prior to study entry will be made for codes indicative of previous use of such devices and women will be excluded the new IUD appears to be a replacement of a previous one. It should be noted that this is not a perfect process because the 5 year intended duration of protection means that codes may be very infrequently used. Identical exclusions, based on the same time periods, will be applied to treatment and comparator groups.

Comparator group

Although the signal under investigation relates specifically to IUDs containing LNG, in this study we investigate the hypothesis that the relevant adverse effects might be caused by systemic exposure to LNG and not related to any other component of the device. Hence a potential comparator group

is formed of women who are fitted with IUDs that do not contain LNG. Product codes for treatment and control groups are given in Annex A and overall annual counts of exposed women are shown in Annex E.

Assessment of continuous exposure

A new contraceptive episode, either treatment or control group, will be defined as starting with the issue date of a prescription for an IUD when no such prescription or indication of usage is found in the preceding full year. To assess continuity of exposure, Read codes for removal of IUDs will be searched and duration of exposure will be reported. Some work on the use of different methods of contraception has been previously done using the THIN dataset (Cea-Soriano et al) and will be reviewed.

Although Read codes exist related to insertion and removal of IUDs, scoping analysis suggests these may not be systematically used or necessarily associated with the correct date (see Annex G) and are hence not used in defining the study period.

Study start and end dates

The study will include women prescribed IUDs between 1 January 2000 and 31 December 2016. Women prescribed IUDs will be included with a minimum of one full year of observation time is available before the prescription date (cohort entry) and prior coding suggests that this is a first exposure to the type of IUD in the relevant arm of the study. Women must be recorded as formally enrolled with a THIN practice meeting the Acceptable Mortality Reporting (AMR) date before study entry. No other data quality measures will be required.

The time to censoring (cohort exit) will be the earliest of: end of exposure (up to five years from the prescription date), the point at which the patient leaves the practice or dies, or the date of last data collection for the practice. The proportion of patients dying should be small but will be reported as a check.

Primary comparison: LNG IUD vs. non-LNG IUD comparison

Analyses will be performed for time from prescription to first occurrence of:

- A Read code diagnosis or prescription indicating anxiety
- A Read code diagnosis indicating a panic attack
- A Read code diagnosis or prescription indicating sleep disturbance
- A Read code diagnosis indicating restlessness
- The first of any of the above Read code diagnoses (composite outcome)

Outcomes will be defined by Read codes or, for anxiety and sleep disturbance, by prescriptions of anxiolytics or sedative-hypnotics. As active anxiety at cohort entry may be associated with read codes reiterating the previous diagnosis, patients with previous anxiety symptoms or treated with anxiolytics at cohort entry will be excluded from the primary analysis. Similarly patients with prior symptoms of other outcomes or treated with sedatives-hypnotics will be excluded from the primary analysis of the relevant outcomes. However, in all cases, secondary analyses will examine the potential effects in the excluded groups. For each outcome, crude incidence of outcomes will be calculated for the treatment and control groups. A Cox proportional hazards regression model will be fitted estimating crude and adjusted hazard ratios with 95% confidence intervals. Adjustment will

be made for all baseline variables. No selection of confounders will be made unless the model fails to converge. The proportional hazards assumption will be checked.

The main comparisons will be LNG IUDs against non-LNG IUDs over the entire exposure period. An exposure period of up to five years from the start of treatment has been defined due to the duration of action of LNG containing IUDs. However, it is possible that natural variation in susceptibility (Renoux et al) or other mechanisms will lead to time variation in hazard ratios. Therefore analysis will also be performed evaluating risk with shorter durations of exposure at 6 months following cohort entry.

Baseline characteristics will be compared between LNG and non-LNG containing products including: age, history of menorrhagia, endometriosis, dysmenorrhea, premenstrual syndrome, perimenopausal symptoms, recent history of childbirth, anaemia, smoking status, alcohol, deprivation, recorded history of any of the outcome events or of depression, co-prescribed medications (anxiolytics, antidepressants, benzodiazepines, antipsychotics, inhalers, oral contraceptives, tranexamic acid); and contraceptive treatment regimen within the previous year. Codes related to IUD treatment discontinuation and any potential problems with use of the IUDs during the study period will be compared between the treatment arms.

Sensitivity analyses and further investigation

- 1. The indication for treatment may vary by age (e.g. the indication for LND IUD in older women may relate to pre-menopausal symptoms). Sensitivity analysis will be conducted examining the effects of age at baseline.
- 2. The effects of treatment with the subgroup of women who gave birth within one year prior to the study will be examined.
- 3. Some Read codes relate to both depression and anxiety. For the primary analysis these will be excluded but sensitivity analysis will be carried out in which they are included.
- Exclusion of women with unclear codes related to insertion or removal of IUDs. See Annex G. The forms of switching and the possibility and possible relationship to outcome events will be described.
- 5. Decriptive analyses will be performed of the associations between study outcome events and also between these events and depressive symptoms.

Assay sensitivity analysis

An association is already documented between depression and exposure to levonorgestrel and an analysis will be carried out to determine if this can be detected in this dataset. This will be carried out prior to the analyses of study outcomes and may be used to improve sensitivity if appropriate.

Code lists

Product codes for LNG and non-LNG IUDs are included in Annex A. Codes related to management of contraceptive devices are included in the Read dictionary and these may give indications about prior use of, removal of or problems with the device. These are included in Annex B.

BNF codes for other classes of contraceptive are included in Annex C. Read codes for events related to anxiety, panic attacks, sleep disorders and restlessness are listed in Annex D. Depression codes for the assay sensitivity analysis are also included.

Annex E Format of analysis datasets

The analysis datasets will be constructed from several data extractions.

D1 The prescription of any LNG IUD and demographic details at the time of prescription will be written to IUDSTUDY_LNGIUDvvvv (where vvvv is the version of THIN.

D2 The prescription of any non-LNG IUD and demographic details at the time of prescription will be written to IUDSTUDY_OTHIUDvvvv (where vvvv is the version of THIN.

D3 From the combined list of IUD prescriptions women will be selected with a full year of observation prior to the first recorded IUD prescription. From these, women with either an IUD removal or replacement code up to and including the prescription date will be excluded. The resulting list of 'first' prescriptions will be named FIRSTIUD.

For any woman listed in FIRSTIUD the following data will be extracted

D4 Any Read code related to anxiety, sleep problems, restlessness or panic. [Note that depression symptoms will also be extracted for a subsidiary analysis]

D5 Any read code related to anaemia, endometriosis, menorrhagia, other menstrual bleeding problems, premenstrual syndrome, dysmenorrhoea, or menopausal problems (without menorrhagia).

PRACID	Practice ID	
PATID	Patient ID	
DOB	Date of birth	
REGDATE	Registration date	
FINALDATE	Patient end of follow-up	
DEATHDATE	Date of death	
GROUP	Study treatment group	
DATEFIRSTTRT	Date of insertion of study IUD	
DATELASTTRT	Date of end of study exposure	
AGE0	Age at insertion of study IUD	
<outcome variables=""></outcome>		
OUTCANY	1 if any of anxiety, restlessness, sleep disorder, panic	
	after insertion.	
TANY	Time (days) of first record of any symptom or EOF	
ANX	1 if any anxiety after insertion	
TANX	Time (days) of first anxiety symptom or EOF	
REST	1 if any restlessness symptom after insertion	
TREST	Time (days) of first restlessness symptom or EOF	
PAN	1 if any panic symptom after insertion	

ANALYSIS DATASET

From the above datasets the following variables will be extracted

TPAN	Time (days) of first panic symptom or EOF	
SLEEP	1 if any sleep problem after insertion

SMOKING	Current recorded smoking status	

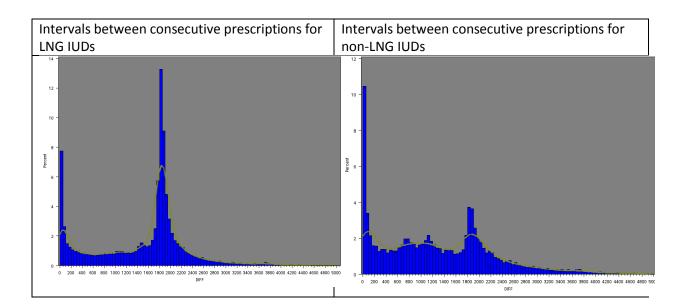

Sensitivity analysis datasets

Two datasets will be created, one for the main analysis (IUDMAIN) and one for the sensitivity analysis in which all women with difficult to interpret Read codes are excluded (IUDSENS) – see discussion under data cleaning (Annex G).

Annex F. Description of populations for selection of treatment and comparator group – based on THIN 1605

Annual numbers of women prescribed contraceptives

EMA PROTOCOL

Annex G Notes on cleaning data

Prescription codes

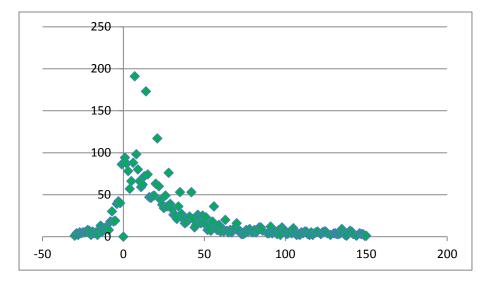

This study relies on accurate use of the codes for LNG and non-LNG IUDs. It is probable that the codes for LNG IUDs are accurately used but the codes that simply denote an IUD could occasionally be used for LNG-IUDs. In the THIN1605 dataset 406 women have codes for both LNG and non-LNG IUDs on the same date, suggesting that some confusion may have occurred. Rather than making arbitrary assumptions, such prescriptions will be omitted from the study.

A smaller number of women have codes for both the 52mg and the 13.5mg LNG IUD on the same day. These cases have been coded as 52mg – which is very much more common than 13.5 – but a column has been added to the dataset (DoseAlt) coding them to 13.5 for sensitivity analyses of any dose related calculations.

IUD associated Read codes

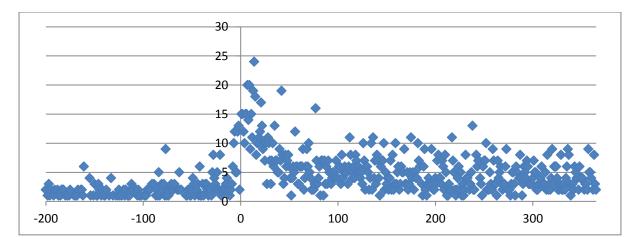

A number of Read codes related to IUDs may also help to determine if a first prescription is truly first use – not that this is essential for the study but it would be required to avoid direct continuity with a previous IUD exposure – and also to determine the duration of use of IUD prescriptions included in the study. These Read codes can be grouped into those related to insertion, removal, replacement, checks on or advice concerning IUDs. Advice codes do not imply current use of a device but checks, removal and replacement do.

These Read codes require some cautious interpretation. The distribution of time intervals between the dates on which an insertion code is recorded and the first recorded prescription of an IUD is shown below. A count of about 7000 at 0 days has been excluded so the scale can be discerned. It is clear that the code is used increasingly from about 30 days before the prescription. Clearly, in these cases the date of recording the insertion is not the date of insertion but, more likely, the date on which the decision to use an IUD was made. This calls into question whether the dates following the prescription can be considered informative regarding when the IUD was inserted or if they are when the GP recorded that the device had been inserted. Given these doubts and the fact that the overwhelming number of prescriptions either do not have an insertion coded or have it coded on the same day, the study start date is set to the prescription date in all cases.

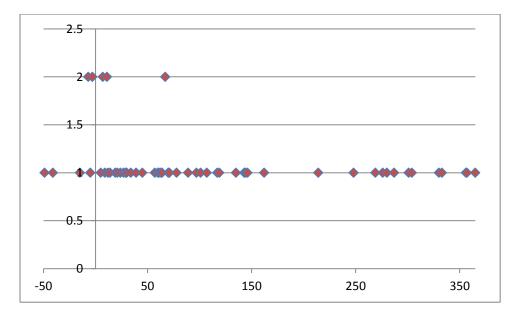

INSERTION v DAYS FROM PRESCRIPTION-PEAK AT T=0 OF 7239 (Not shown)

REMOVAL v DAYS FROM PRESCRIPTION - PEAK AT T=0 OF 499 (Not shown)

REPLACEMENT v DAYS FROM PRESCRIPTION - PEAK AT T=0 OF 129 (Not shown)

A further confusing observation is that a number of cases exist where a code for insertion is used that is not adjacent to any prescription code. There are 34005 Read codes for insertion and only 12866 are within 30 days of a prescription for an IUD. This should be viewed in the context of 212022 such prescriptions. There is no way of using these Read codes to add to the study population as they do not reveal the type of IUD. However, they may inform concerning the use of IUDs. However, it is also possible that they reflect discussion about potential use of an IUD that was eventually not adopted.

Read codes for removal also start to increase shortly before the prescription date and show a brief peak before settling to a fairly constant level. The pre-prescription codes probably indicate removal of a previous device – there is a count of about 500 on day 0 which is not shown in the graph. However, removal after the prescription is less clear. It could be removal of a previous device preparatory to fitting the new IUD or it could reflect a problem with the new device. The difficulty of accurately interpreting both insertion and removal codes suggests that the uncertainty might be best handled by a sensitivity analysis as follows:

1. All patients with a removal or replacement code before or on day 0 would be excluded from the study.

2. Patients with removal or insertion codes soon after the prescription date would be included in the main analysis. Such patients would be excluded in a sensitivity analysis. Removal codes 6 months or more following the prescription will be taken literally to reflect the end of exposure and the woman retained in the main analysis.

If such a code, or one concerning removal or checking of an IUD, has been recorded in the year before the first recorded prescription of an IUD it is assumed that the woman is already using an IUD and is excluded from the study. There are a number of women for whom the insertion date is recorded a few days <u>before</u> the prescription. It is possible that this is some form of miscoding but these women are also removed. Likewise, if a removal or replacement is recorded on the same day as the prescription these cases are excluded.

The end of a period of use of an IUD can be indicated by a removal code or a further insertion or replacement code or prescription of another contraceptive. It is also possible that the removal will not be indicated in any way. The doubts about the use of these codes soon after the prescription makes them very difficult to use. These cases will thus be handled via the above sensitivity analysis.
