

## **EPIDEMIOLOGY STUDY PROTOCOL**

**Serious Liver Injury And Interstitial Lung Disease Occurrences In Patients  
Diagnosed With Atrial Fibrillation Treated With Selected Anti-Arrhythmics**

**Dronedarone**

**Study type:** Post Authorization safety Study

**Company:** Sanofi

**Version Number/Status:** Final v1

**Study number:** Drone\_C\_05917

**This study will be conducted in accordance with  
Sanofi standard operating procedures for GPE epidemiologic studies**

**Date:** 09-May-2017

**Total number of pages** 12 + (Appendices)

**PASS information:**

## LIST OF APPENDICES

*Appendix 1* – Study Report: DOD Database

*Appendix 2* – Study Report: HIRD Database

## 1 SUMMARY OF STUDIES

**Title:** Serious Liver Injury and Interstitial Lung Disease Occurrences in Patients Diagnosed with Atrial Fibrillation Treated with Selected Anti-Arrhythmics

## 2 RATIONALE AND BACKGROUND

Dronedarone (Multaq<sup>®</sup>) is an anti-arrhythmic drug with effects from all four classes of the Vaughan Williams classification indicated for treatment of patients with non-permanent Atrial Fibrillation (AF). Dronedarone was initially approved by the FDA on 1 July 2009 for marketing in the United States. It is currently marketed in 32 countries in the Americas, Europe, and Asia.

Post-marketing analysis of spontaneous reports associated with dronedarone use identified safety signals related to *serious liver injury/disease* (SLD) and *interstitial lung disease* (ILD), which were also seen in association with the other anti-arrhythmics, notably amiodarone. In order to examine associations of dronedarone and comparator anti-arrhythmic drugs with these signaled events, Sanofi contracted with The Degge Group, Ltd. (Degge) to conduct a retrospective cohort study among adults in a real-world setting where dronedarone is approved for non-permanent AF.

## 3 RESEARCH QUESTION AND OBJECTIVES

The overall goals were to:

- Describe cohorts of patients treated for AF with dronedarone and comparator anti-arrhythmic drugs, and identify possible SLD and ILD outcomes in two different healthcare databases.
- Measure occurrences of SLD and ILD in cohorts of patients treated with dronedarone versus comparators treated with other anti-arrhythmic drugs.

Specific primary objectives were to:

- Compare rates of hospitalized **SLD** in dronedarone-exposed patients to those of patients treated for AF with amiodarone, sotalol, flecainide, dofetilide, or propafenone.
- Compare rates of hospitalized **ILD** in dronedarone-exposed patients to those of patients treated for AF with amiodarone, sotalol, flecainide, dofetilide, or propafenone.

## 4 STUDY DESIGN

Observational retrospective cohort study.

### 4.1 DATA SOURCES

The primary analysis for this study was conducted in the US Department of Defense, Military Health System Database (DoD) [Appendix 1](#). The Military Health System provides two types of care, direct care and purchased care, to its beneficiaries. Direct care is provided through a network of military hospitals and clinics, and purchased care is delivered by civilian providers financed through managed care contracts and fee-for-service reimbursements. Direct care accounts for 37% of all care provided. All administrative events generated by either a direct care or purchased care encounter are tracked in the central Military Health System Data Repository. The DoD database also includes records from the military's electronic medication ordering system called the Pharmacy Data Transaction System (PDTS). PDTS includes electronically coded dispensing details of both direct care and purchased care outpatient medication orders, including the prescribed drug name and National Drug Codes (NDCs), dose, quantity, refills and prescribing provider.

A parallel analysis was conducted in the HealthCore Integrated Research Database (HIRD) [Appendix 2](#). The HIRD<sup>SM</sup> is a broad, clinically rich and geographically diverse spectrum of longitudinal insurance claims data from plans in the Northeastern, Mid-Atlantic, Southeastern, Midwest, Central, and Western regions of the United States. It contains data on eligibility, medical, and pharmacy claims on more than 45 million members of one of the largest commercially insured populations in the United States. In addition, electronic laboratory results data are available for a subset of approximately 10 million patients. Outpatient medications are coded with NDCs as well as with Generic Product Indicators (GPI), which include the drug name, dosage form and drug strength.

### 4.2 STUDY PERIOD

The study period was 20 July 2008 to 30 September 2014.

### 4.3 SUBJECTS AND STUDY SIZE

*Overall patient inclusion criteria* for both studies were:

- 365 days of continuous eligibility in the health plan prior to and including the Index Date;
- A new prescription for any one of the following six anti-arrhythmic agents: **dronedarone**, **amiodarone**, **sotalol**, **flecainide**, **dofetilide**, or **propafenone**, dispensed between 20 July

2009 (the dronedarone launch date in the US) and 31 March 2014. The first of these drugs of interest dispensed during the patient selection period determined a patient's study cohort assignment and was referred to as the patient's Index Drug. The date on which that first study medication was dispensed was defined as the patient's Index Date, and the 365 days prior to and including the patient's Index Date defined their baseline period;

- Diagnosed with atrial fibrillation (AF, ICD-9-CM diagnosis code 427.31) during the baseline period;
- No use of the Index Drug during the baseline period. Use of non-index study drugs during the baseline period was allowed;
- Patient aged 18 years or older as of their Index Date.

*Overall patient exclusion criteria* for both studies were:

- Unknown gender;
- Index Drug use during the baseline period;
- Multiple study drugs on the Index Date;
- Less than 365 days of continuous eligibility in the health plan prior to and including the Index Date;
- Absence of a diagnosis of AF during the baseline period;
- A diagnosis of cancer, organ transplant, or HIV during the baseline period;
- Women who were pregnant during the 280 days prior to and including the Index Date, or became pregnant during the 280 days following the Index Date, or
- Date of death preceding Index Date.

*Outcome specific criteria* were applied to patients meeting the overall selection criteria to create separate SLD and ILD study populations. Patients included in the respective study populations could have no history of the relevant outcome of interest (i.e. SLD or ILD) during the 365 days prior to the Index Date. The SLD specific screening excluded patients with a history of the SLD outcome of interest, as well as patients with history of viral hepatitis, other related hepatitis or selected hereditary conditions (e.g. glycogenosis, alpha-1-antitrypsin deficiency). The ILD specific screening excluded patients with a history of the ILD outcome of interest and also excluded patients with history of pneumonia or sarcoidosis prior to their Index Date.

A total of 51,390 DoD patients met the general screening criteria. Following outcome specific screening 47,671 patients were retained in the DoD SLD study population, and 41,591 in the DoD ILD study population. There were 35,407 HIRD patients after general screening, and totals of 32,853 patients and 29,780 patients in the SLD and ILD study populations, respectively, after outcome specific screening.

DoD and HIRD outcome analyses were conducted in datasets generated from the corresponding study populations by using PS matching to minimize variability in baseline risk factors. As the numbers of patients in the dofetilide and propafenone drug groups did not meet the required sample size for the desired statistical power in either database, these two cohorts were eliminated from both the DoD and HIRD study populations prior to generating the PS-matched analysis datasets. SLD and ILD PS-matched analysis datasets for the DoD study contained 16,492 patients (4,123 per drug cohort) and 16,348 patients (4,087 per drug cohort), respectively. The HIRD analysis datasets contained totals of 11,084 SLD patients (2,771 per drug cohort) and 11,544 ILD patients (2,886 per drug cohort).

#### **4.4 STUDY VARIABLES**

Anonymized patient level records pertaining to patient demographics, inpatient and outpatient diagnoses and procedures, and pharmacy dispensing records were used to develop the measures used in the analyses.

#### **4.5 OUTCOME EVENTS**

Suspected SLD and ILD outcome events were defined as the first inpatient occurrence during the relevant risk period, in an acute care hospital or skilled nursing facility that had a discharge diagnosis or procedure code that met the outcome event definition. Suspected SLD outcome events were identified in the interval beginning the day after a patient's Index Date, and extending through the earliest occurrence of an SLD outcome, end of health plan eligibility, death or the end of days' supply of the last continuous prescription beginning with the Index Date. The risk period for identification of ILD events began the day after a patient's Index Date and extended to the earliest occurrence of an ILD outcome, end of health plan eligibility, death, or the end of the study.

Suspected outcome events in both the DoD and HIRD databases were adjudicated by two panels of three expert clinicians per panel (one panel for liver and one for pulmonary events). Each group of three panel members reviewed and adjudicated relevant profiles (SLD or ILD) for both DoD and HIRD databases. Adjudicators manually reviewed profiles consisting of up to one year of chronological patient history surrounding the suspected events, in order to determine whether the identified cases were valid outcome events. All patient records were de-identified, and panelists were blinded to patients' specific study drug exposures. Adjudicators separately reviewed each case and independently assigned a determination of "Yes," "No" or "Indeterminate" to the first inpatient occurrence of the outcome event. Unanimous assessments were considered as final decisions. When adjudicators differed in their initial determinations, formal meetings were held to review the cases. The chairperson facilitated the discussion where each adjudicator explained their initial determination. Adjudicators then indicated their final determination. The final decision for each suspected outcome event was based on a majority vote.

If each of the three adjudicators reached a different conclusion after discussion, then the case was considered “Indeterminate.”

## 5 ANALYTICAL APPROACH

Baseline risk factors relevant to each outcome were used to develop logistic regression models from which propensity scores (PS) were generated (predicting the probability of dronedarone exposure). Separate propensity scores were calculated for each outcome analysis (SLD, ILD). For each analysis, an attempt was made to find a PS-matched patient from each of the three comparator cohorts for each patient in the dronedarone cohort. PS matching was conducted using a nearest-neighbor-within-caliper matching algorithm, and was conducted without replacement. A qualifying matched case from each comparator cohort was required in order for a dronedarone case to be included in the analysis dataset.

Incidence rates of valid outcome events (cases adjudicated as “Yes”) were calculated per 1,000 person-years of exposure (SLD) or follow-up (ILD) stratified by study drug cohort. Graphs displaying separate Kaplan-Meier survival curves for each exposure group were also prepared, with one graph for each outcome event (i.e. SLD, ILD). The log-rank test was used to test the significance of differences between the dronedarone cohort and each comparator cohort.

Survival analysis for each outcome was carried out using separate Cox proportional-hazards regression models, with exposure group (dronedarone as the reference drug) as the main independent variable, and incorporating confounders that remained severely unbalanced after propensity score matching.

Due to ILD’s non-specific clinical presentations, which can include non-specific chest x-ray findings, as well as cough, a broad range of diagnoses may be assigned to ILD patients. In consideration of these complexities three sensitivity analyses, designed to determine any effect on the results from modifications of the definition of ILD and/or length of the risk period, were conducted in the DoD data to supplement the primary ILD analysis.

Two definitions of ILD were used for the analyses:

- The Narrow definition of ILD used a set of ICD-9-CM diagnosis codes described in a systematic review for the FDA’s Mini-Sentinel Project by Natalie Jones et al., 2012.
- The Broad definition of ILD expanded the Narrow definition by adding two diagnosis codes (495.9 Unspecified allergic alveolitis and pneumonitis, and 518.82 Other pulmonary insufficiency, not elsewhere classified).

Two risk periods were defined for the analyses:

- **ILD Risk Period 1** was the period that began the day after the Index Date and continued until the earliest occurrence of an ILD outcome, the end of MHS eligibility, death, or the end of follow-up.
- **ILD Risk Period 2** had a shorter maximum observation period. Beginning the day after the Index Date, **ILD Risk Period 2** ended at the earliest occurrence of an ILD outcome, the end of MHS eligibility, death, or the end of the index treatment episode.

## 6 RESULTS

Similar results were found in the cohort studies conducted in the two individual data sources.

Few suspected SLD cases were identified in either database (32 in the DoD database (see [Appendix 1](#)) and 16 in the HIRD database (see [Appendix 2](#)), and none received a “Yes” adjudication result. As no outcome events were confirmed as valid cases by the adjudicators, there were no differences in rates of SLD by study drug cohort in either analysis.

Of the 113 suspected cases of ILD identified in the DoD database, 52 were confirmed as “Yes” by the ILD adjudication panel. The amiodarone cohort was the only comparator group with a significantly different rate of ILD from that of dronedarone users. The amiodarone cohort had a significantly higher incidence rate of ILD with 2 cases per 1,000 person-years of follow-up, versus 0.8 cases per 1,000 person-years of follow-up in the dronedarone group. Amiodarone was associated with an adjusted hazard ratio for ILD of 2.5 (95% CI=1.1-5.3) relative to dronedarone over the course of the follow-up period. Results of the three ILD sensitivity analyses conducted in the DoD did not differ substantially from those of the primary ILD analysis conducted in that dataset.

In the HIRD study, 20 of the 33 suspected ILD cases were adjudicated as “Yes.” This equated to 1.3 cases per 1,000 person-years of follow-up among the HIRD dronedarone patients. ILD incidence rates in dronedarone users did not differ significantly from any other drug groups in the HIRD study, and none of the adjusted hazard ratios for ILD relative to dronedarone was significantly different from 1.

## 7 DISCUSSION

The granular longitudinal DoD and HIRD databases allowed extensive identification of pre-and post-exposure events in the selected cohorts, as well as propensity score matching to create analysis datasets that were balanced across study drug cohorts with respect to baseline risk factors. Suspected cases of SLD and ILD in the analysis datasets were carefully and

independently evaluated by specialty (hepatic and pulmonary) clinical adjudicators to determine the likelihood of being valid outcome events.

The SLD adjudicators determined that none of the 48 suspected cases of SLD found in the propensity score matched datasets was confirmed as SLD. Thus, there were no differences in rates of SLD between dronedarone and comparator drug users in either the DoD or HIRD data.

The ILD adjudicators confirmed 52 (46%) of the 113 cases of suspected ILD in the DoD study, and 20 (60.6%) of the 33 suspected cases in the HIRD study, as valid interstitial lung disease events. The difference in proportions of confirmed cases between the databases was not statistically significant ( $\chi^2=2.2$ ,  $p=0.14$ ). In the DoD study, the amiodarone cohort had 2.5 times the risk of a confirmed ILD event over the course of the follow-up period compared to the dronedarone cohort. There were no significant differences in rates of confirmed ILD events between the dronedarone patients and the patients treated with other anti-arrhythmics in the HIRD study.

In summary, these two retrospective cohort studies found no evidence of increased risk of SLD or ILD in AF patients treated with dronedarone versus patients using comparator drugs to treat AF.

## 1. ABSTRACT

### Title

SERIOUS LIVER INJURY AND INTERSTITIAL LUNG DISEASE OCCURRENCES IN PATIENTS DIAGNOSED WITH ATRIAL FIBRILLATION TREATED WITH SELECTED ANTI-ARRHYTHMICS

### Keywords

Observational retrospective cohort study, dronedarone versus other anti-arrhythmics, serious liver diseases, interstitial lung disease

### Rationale and background

Dronedarone (Multaq<sup>®</sup>) is an anti-arrhythmic drug with effects from all four classes of the Vaughan Williams classification indicated for treatment of patients with non-permanent Atrial Fibrillation (AF).<sup>1</sup> Dronedarone was initially approved by FDA on 1 July 2009 for marketing in the United States. It is currently marketed in 32 countries in the Americas, Europe, and Asia.

Post-marketing analysis of spontaneous reports associated with dronedarone use identified safety signals related to *serious liver injury/disease* (SLD), and *interstitial lung disease* (ILD), which are also seen in association with the other treatments, notably amiodarone.<sup>2</sup> In order to examine associations of dronedarone, and comparator anti-arrhythmic drugs, with these signaled events Sanofi contracted with The Degge Group, Ltd. (Degge) to conduct a retrospective cohort study among adults in a real-world setting where dronedarone is approved for non-permanent AF.

Treatment goals for AF include ventricular rate control, anticoagulation to prevent thromboembolism, and *elective* conversion to normal sinus rhythm and maintenance of sinus rhythm, depending on the clinical state of the patient.<sup>3</sup> Initial treatment involves either ventricular rate control or rhythm control. If ventricular rate control is the initial treatment strategy, rhythm control is not considered a therapeutic objective. On the other hand, if rhythm control is the initial treatment strategy, concomitant management of rate control is also addressed. Regardless of initial treatment strategy, antithrombotic therapy is considered. Patient response to the initial therapy guides further treatment decision-making.

Guidelines exist for the treatment of AF targeting rate and rhythm control (as well as anticoagulation) although some medications such as amiodarone used for treatment are not indicated for AF.<sup>4,5</sup> Rate control therapy consists of treatment with beta-blockers, calcium channel blockers, and digoxin, while amiodarone and other anti-arrhythmic agents are used for rhythm control.

## Research question and objectives

The overall goals were to:

- Describe cohorts of patients treated for AF with dronedarone and comparator drugs, and identify possible **SLD** and **ILD** outcomes in two different healthcare population databases.
- Measure occurrences of **SLD** and **ILD** in cohorts of patients treated with dronedarone versus comparators treated with other anti-arrhythmic drugs.

Specific primary objectives were to:

- Compare rates of hospitalized **SLD** in dronedarone-exposed patients to those of patients treated for AF with amiodarone, sotalol, flecainide, dofetilide, or propafenone.
- Compare rates of hospitalized **ILD** in dronedarone-exposed patients to those of patients treated for AF with amiodarone, sotalol, flecainide, dofetilide, or propafenone.

## Study design

Observational retrospective cohort study.

## Setting

US Department of Defense, Military Health System Database

## Subjects and study size

Patients were active participants in the Military Health System between 20 July 2008 and 30 September 2014. They were required to be  $\geq$  age 18 and have a first-time prescription for their anti-arrhythmic therapy for atrial fibrillation between 20 July 2009 and 31 March 2014 for inclusion in the study population. In addition, they were required to have at least 365 days of continuous enrollment prior to the index prescription fill, during which time a diagnosis of AF had to appear. Additional screening for the specific outcome study populations (SLD and ILD) were applied to remove patients who might have experienced the outcome prior to their Index Date.

A total of 47,671 patients were screened into the initial pool of patients for the SLD analysis. There were 41,591 patients screened into the pool of patients for the primary ILD analysis.

## Variables and data sources

Health ResearchTx (HRTx), a health research organization, has a unique partnership with the US Department of Defense to leverage the DoD MHS in order to improve health outcomes, lower costs, and increase force readiness. HRTx facilitated Degge's access to the DoD data through a secured server, using an encrypted login and password. HRTx obtained US Department of Defense Institutional Review Board approval required for this study, Protocol #NMCP.2014.0044.

Anonymized patient level records from the MHS data pertaining to patient demographics, hospital and outpatient diagnoses and procedures, and pharmacy dispensing records were used to develop the measures used in the analyses.

## Results

Results from this retrospective cohort study in two large electronic health record (EHR) population databases show that the incidence of SLD and ILD in patients with AF treated with dronedarone are not different than in patients using most comparator drugs. Few SLD cases were identified, and none were adjudicated as confirmed SLD. Less than 1 case of ILD per 1,000 person-years of exposure was estimated in dronedarone users. Amiodarone was associated with an adjusted risk of ILD 2.5 times higher than that of dronedarone, with a point estimate of 2 cases per 1,000 person-years of follow-up.

## Discussion

In these granular longitudinal datasets, the selected cohorts allowed extensive identification of pre- and post-exposure events, as well as propensity score matching to assure the cohorts were comparable as to baseline risk factors. The resulting possible cases of SLD and ILD were carefully and independently evaluated by specialty (hepatic and pulmonary) clinical adjudicators to determine the likelihood of being valid outcome events.

Adjudicators determined that none of the 32 suspected cases of SLD found in the propensity score matched dataset were confirmed SLD (though one was indeterminate). Thus, there were no differences in the rates of SLD between the propensity score matched cohorts.

There were 113 suspected cases of ILD in the corresponding propensity score matched dataset. Adjudicators confirmed 52 of those cases as interstitial lung disease events. Patients in the propensity score matched ILD population taking amiodarone had a 2.5 times higher risk than the dronedarone patients over the course of the follow-up period (95% CI:1.1-5.3) of a confirmed case of ILD.

Overall results from this retrospective cohort study show that the incidence of SLD and ILD in patients with AF treated with dronedarone are not different than in patients using comparator anti-arrhythmic drugs.

## 5. RATIONALE AND BACKGROUND

Dronedarone (Multaq<sup>®</sup>) is an anti-arrhythmic drug with effects from all four classes of the Vaughan Williams classification indicated for treatment of patients with non-permanent Atrial Fibrillation (AF).<sup>1\*</sup> Dronedarone was initially approved by FDA on 1 July 2009 for marketing in the United States. It is currently marketed in 32 countries in the Americas, Europe, and Asia.

Post-marketing analysis of spontaneous reports associated with dronedarone use identified safety signals related to *serious liver injury/disease* (SLD), and *interstitial lung disease* (ILD), which are also seen in association with the other treatments, notably amiodarone.<sup>2</sup> In order to examine associations of dronedarone, and comparator anti-arrhythmic drugs, with these signaled events Sanofi contracted with The Degge Group, Ltd. (Degge) to conduct a retrospective cohort study among adults in a real-world setting where dronedarone is approved for non-permanent AF.

Treatment goals for AF include ventricular rate control, anticoagulation to prevent thromboembolism, and *elective* conversion to normal sinus rhythm and maintenance of sinus rhythm, depending on the clinical state of the patient.<sup>3</sup> Initial treatment involves either ventricular rate control or rhythm control. If ventricular rate control is the initial treatment strategy, rhythm control is not considered a therapeutic objective. On the other hand, if rhythm control is the initial treatment strategy, concomitant management of rate control is also addressed. Regardless of initial treatment strategy, antithrombotic therapy is considered. Patient response to the initial therapy guides further treatment decision-making.

Guidelines exist for the treatment of AF targeting rate and rhythm control (as well as anticoagulation) although some medications such as amiodarone used for treatment are not indicated for AF.<sup>4,5</sup> Rate control therapy consists of treatment with beta-blockers, calcium channel blockers, and digoxin, while amiodarone and other anti-arrhythmic agents are used for rhythm control.

---

\* Atrial flutter (AFL) was included as an indication on the dronedarone product label prior to December 2011. Approximately 0.6% of patients in both the Serious Liver Injury/Disease Study Cohort and the Interstitial Lung Disease Study Cohort had an AFL diagnosis only (data not shown). Given that small percentage, it was decided to exclude the AFL indication from this study.

## 6. RESEARCH QUESTIONS AND STUDY OBJECTIVES

The overall goals were to:

- Describe cohorts of patients treated for AF with dronedarone and comparator drugs, and identify possible **SLD** and **ILD** outcomes in two different healthcare population databases.
- Measure occurrences of **SLD** and **ILD** in cohorts of patients treated with dronedarone versus comparators treated with other anti-arrhythmic drugs.

Specific primary objectives were to:

- Compare rates of hospitalized **SLD** in dronedarone-exposed patients to those of patients treated for AF with amiodarone, sotalol, flecainide, dofetilide, or propafenone.
- Compare rates of hospitalized **ILD** in dronedarone-exposed patients to those of patients treated for AF with amiodarone, sotalol, flecainide, dofetilide, or propafenone.

## 7. AMENDMENTS AND UPDATES

| No. | Date     | Section of study protocol                                                   | Amendment or update                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|     |      | Appendix F – PROPENSITY SCORE MODEL DEVELOPMENT: SELECTION OF VARIABLES        | Hepatology specialty (DoD only) was included along with Gastroenterology regarding specialty visits for SLD propensity score modeling.                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## 8. RESEARCH METHODS

### 8.1 STUDY DESIGN

An observational retrospective cohort design was used to estimate rates of SLD and ILD occurring after treatment in dronedarone and comparator drug cohorts. Three sensitivity analyses were conducted for the ILD outcome, by alternately modifying the ILD definition and risk period.

An Epidemiology Steering Committee (ESC) monitored study progress. Two independent adjudication panels (IAPs), one for each outcome event, reviewed and adjudicated suspected outcome events. The ESC and two IAPs each had their own charter describing assigned roles and responsibilities. (See [Appendix 2.](#))

### 8.2 SETTING

Degge conducted the study, in collaboration with Sanofi, using data from the US Department of Defense Military Health System (MHS) database (DoD). A parallel study was conducted, under the supervision of Degge, in the HealthCore Integrated Research Database (HIRD<sup>SM</sup>). Findings from these studies provide insight into the risk of SLD and ILD in two different non-interventional, “real world” settings. The analyses conducted in the HIRD are provided in a separate report.

Prior to conducting the retrospective cohort studies, surveillance of the population exposed to dronedarone from the time of its approval (20 July 2009) was conducted in both databases in order to determine the feasibility of detecting, characterizing, and quantifying the occurrence of SLD and ILD outcome events associated with use of the drug. Degge coordinated both surveillance programs, which required:

1. Tracking, by quarter, the uptake of dronedarone and comparator drugs in the general population;
2. Developing definitions for suspected SLD and ILD outcome events;
3. Identifying suspected cases of SLD and ILD in patients with prescription dispensings for dronedarone and comparator drugs; and
4. Determining when sufficient numbers of users of dronedarone and comparator drugs were identified to conduct the requested epidemiological analysis.

See [Appendix 1](#) for a complete description of the dronedarone surveillance program.

## 8.2.1 United States Department of Defense, Military Health System Electronic Health Record System

The source population for this study included all beneficiaries in the MHS between 20 July 2008 and 30 September 2014. As a single payer system MHS provides uniform medical coverage and pharmacy benefits for more than 100 million covered lives, including both active duty and retired military members and their families (beneficiaries). Active duty members comprise approximately 17% of the MHS covered population.

DoD includes over 30 billion archived records, 5 billion online health records spanning more than 11 years, 20 years of ePrescribing and comparable decades of prescription, inpatient and outpatient data. Records of veterans who receive medical coverage through the Veterans Administration are not captured in the DoD database.

The MHS provides two types of care to its beneficiaries. *Direct care* is provided through a network of military hospitals and clinics, and *purchased care* is delivered by civilian providers financed through managed care contracts and fee-for-service reimbursements. Direct care accounts for 37% of all care provided. All administrative events generated by either a direct care or purchased care encounter are tracked in the central MHS Data Repository (MDR). Examples of data recorded in the MDR include patient demographic data, provider information (provider ID, specialty, and facility), diagnostic codes (ICD-9-CM codes for outpatient visits; Diagnosis-Related Group (DRG) codes for inpatient stays) and Current Procedural Terminology (CPT<sup>®</sup>) codes for procedures. Extensive patient information including address, age, race, rank, and active duty status is also stored within the MDR via connections with the Defense Eligibility Enrollment Reporting System (DEERS). DoD also includes records from the military's electronic medication ordering system called the Pharmacy Data Transaction System (PDTS). PDTS includes electronically coded dispensing details of both direct care and purchased care outpatient medication orders, including the prescribed drug name and National Drug Code (NDC), dose, quantity, refills and prescribing provider.

### Health ResearchTx, LLC / Department of Defense

Health ResearchTx (HRTx), a health research organization, has a unique partnership with the US Department of Defense to leverage the DoD MHS system in order to improve health outcomes, lower costs, and increase force readiness. HRTx facilitated Degge's access to the DoD data through a secured server, using an encrypted login and password. HRTx obtained US Department of Defense Institutional Review Board approval required for this study, Protocol #NMCP.2014.0044.

## 8.3 SUBJECTS

### 8.3.1 Study Period

The study start date was 20 July 2008, and the study end date was 30 September 2014. Patients were selected for inclusion in the study drug cohorts on the basis of their drug dispensing records between 20 July 2009 and 31 March 2014. See [Figure 1](#).

**Figure 1. Patient Selection**

### 8.3.2 General Inclusion / Exclusion Criteria

The following criteria were used for the initial screening of patients for inclusion in the *Final study drug cohorts*.

#### 8.3.2.1 Inclusion Criteria

- 365 days of continuous eligibility in the MHS prior to and including the Index Date;
- A new prescription for any one of the following six anti-arrhythmic agents: **dronedarone**, **amiodarone**, **sotalol**, **flecainide**, **dofetilide**, or **propafenone**, dispensed between 20 July 2009 (the dronedarone launch date in the US) and 31 March 2014 (See [Appendix 3](#)). The first of these drugs of interest dispensed during the patient selection

period determined a patient's **study cohort** assignment and was referred to as the patient's Index Drug. The date on which that first study medication was dispensed was defined as the patient's Index Date, and the 365 days prior to and including the patient's Index Date defined their baseline period;

- Diagnosed with atrial fibrillation (AF, ICD-9-CM diagnosis code 427.31) during the baseline period\*;
- No use of the Index Drug during the baseline period. Use of non-index study drugs during the baseline period was allowed;
- Patient aged 18 years or older as of their Index Date.

#### **8.3.2.2 Exclusion Criteria**

- Unknown gender;
- Index Drug use during the baseline period;
- Multiple study drugs on the Index Date;
- Less than 365 days of continuous eligibility in the MHS prior to and including the Index Date;
- Absence of a diagnosis of AF during the baseline period;
- A diagnosis of cancer, organ transplant, or HIV during the baseline period (See [Appendix 4](#)).
- Women who were pregnant during the 280 days prior to and including the Index Date, or became pregnant during the 280 days following the Index Date [Appendix 4](#);
- Date of death preceding Index Date.

---

\* Atrial flutter (AFL) was included as an indication on the dronedarone product label prior to December 2011. Approximately 0.6% of patients in both the Serious Liver Injury/Disease Study Cohort and the Interstitial Lung Disease Study Cohort had an AFL diagnosis only (data not shown). Given that small percentage, it was decided to exclude the AFL indication from the inclusion screening criteria of this study.

### 8.3.3 Outcome Specific Screening

Following the general screening, separate study drug cohorts were identified for each outcome of interest (Serious Liver Disease [SLD] and Interstitial Lung Disease [ILD]). Baseline records of patients in the *Final study drug cohorts* were screened to exclude those with pre-Index Date occurrences and/or related conditions relevant to the respective hepatic or pulmonary outcomes. The additional criteria were applied to better ensure that outcomes identified post-index would be truly incident events and not recurrences from the baseline period. Specific conditions for which each group of study cohorts were screened are described below.

#### 8.3.3.1 Serious Liver Injury Outcome (SLD) Cohort Screening

To create the *SLD study cohorts* – patients in the *Final study drug cohorts* with any baseline occurrence (inpatient or outpatient) regardless of institution type (e.g., acute care hospital, skilled nursing facility, hospice, etc.) of the following conditions were excluded.

- History of Serious liver injury/disease;
- History of viral hepatitis; or
- History of hereditary conditions (e.g., Wilson’s disease, hemochromatosis, galactosemia, Alagille syndrome, alpha-1 antitrypsin deficiency, or type 1 glycogen storage disease).

(See [Appendix 5](#) for specific codes used to identify the conditions.)

Patients remaining after the SLD screening formed the *SLD study cohorts*.

#### 8.3.3.2 Interstitial Lung Disease Outcome (ILD) Cohort Screening

ILD may manifest itself within a few days or weeks after exposure, or take longer to appear (e.g., months or years). Furthermore, due to ILD’s non-specific clinical presentations, which can include non-specific chest x-ray findings, as well as cough, a broad range of diagnoses may be assigned to ILD patients. In consideration of these complexities, the primary ILD analysis was supplemented by three sensitivity analyses designed to determine any effect on the results from modification of the length of the risk period and/or ILD definition.

Given the planned sensitivity analyses, two definitions of ILD were used. The first was based on an established definition and is referred to as the ILD Narrow definition ([Section 8.4.4.2](#)). The second expanded the narrow definition with the addition of two diagnosis codes and is referred to as the ILD Broad definition ([Appendix 13](#)).

The *ILD Narrow definition study cohorts* were created by excluding patients in the *Final study drug cohorts* with any baseline occurrence (inpatient or outpatient) regardless of institution type (e.g., acute care hospital, skilled nursing facility, hospice, etc.) of the following diseases:

- History of ILD Narrow definition;

- History of pneumonia; or
- History of sarcoidosis.

(See [Appendix 6](#) for specific codes used to identify the conditions):

Patients remaining after the ILD Narrow definition screening formed the *ILD Narrow definition study cohorts*, which was used for the primary ILD analysis.

## 8.4 VARIABLES

### 8.4.1 Treatment Episode

A *treatment episode* was defined as a continuous period starting on the date a study drug was dispensed, and continuing for the duration of the last refill's days' supply. In cases where there was a gap of fewer than 30 days between the date on which a days' supply ended and the dispensing date of a subsequent refill for the same drug, the subsequent refill was considered a continuation of the first treatment episode.

A **treatment episode** ended on the date when the days' supply for the last refill in the episode was calculated to run out, plus 30 days (added as a risk window to account for potential non-compliance or missed doses). In cases where a different study drug was dispensed (treatment switch) prior to the end of a treatment episode (i.e., a treatment episode for the new drug begins), the end date of the first episode was changed to the day preceding the start of the treatment switch. A treatment episode end date was also changed to the earliest of the date of death, end of MHS eligibility or end of study, should any of those events have occurred prior to the calculated end of a treatment episode.

The **index treatment episode** was defined as the treatment episode that began on a patient's Index Date. See [Appendix 7 - Figure 1](#).

### 8.4.2 Follow-up Period

The **follow-up period** references the amount of time after their Index Date for which records were available for each patient. The **follow-up period** started the day after the Index Date and ended at the first occurrence of either the end of the study period, end of MHS eligibility, or death.

### 8.4.3 Risk Period

The **risk period** was the interval of time for which patient records were examined to identify suspected outcomes. The sensitivity analyses conducted for the ILD outcome involved identification of ILD outcomes in two different Risk Periods, which will be referred to as *ILD risk Period 1* and *ILD risk period 2*. The *SLD risk period* and *ILD risk period 1* (used for the ILD primary analysis) are defined below. *ILD risk period 2* is defined in [Appendix 7](#), which reports on the ILD sensitivity analyses.

***SLD risk period*** was defined as the period beginning the day after the Index Date and continuing until the earliest occurrence of an SLD outcome, end of MHS eligibility, death, or the end of the index treatment episode. See [Appendix 7 - Figure 1](#).

***ILD risk period 1*** was defined as the period that began the day after the Index Date and continued until the earliest occurrence of an ILD outcome, the end of MHS eligibility, death, or the end of follow-up. See [Appendix 7 - Figure 2](#).

***ILD risk period 2*** was defined as the period that began the day after the Index Date and continued until the earliest occurrence of an ILD outcome, end of MHS eligibility, death, or the end of the index treatment episode.

### 8.4.4 Outcome Events of Interest

Outcome events of interest for the primary analyses were incident cases associated with a hospitalization (and not a related outpatient code) for:

- Serious liver injury/disease during the *SLD risk period*;
- Interstitial lung disease, defined by the ILD Narrow Definition, during *ILD risk period 1*.

As each outcome event was analyzed separately, an occurrence of one outcome of interest did not censor follow up for the other (e.g., an SLD occurrence did not preclude following an eligible patient for a subsequent occurrence of ILD). Only the first hospitalized outcome event occurrence was assessed in each of the respective outcome event analyses. In the context of this study, a hospitalization was defined as an inpatient stay at an acute care hospital or skilled nursing facility.

#### 8.4.4.1 Serious Liver Injury/Disease (SLD) Outcome Event Definition

Suspected SLD outcome events were identified by inpatient ICD-9-CM diagnosis / procedure codes or CPT<sup>®</sup> procedure codes (see [Appendix 8](#)). Two groups of codes, referred to as **Group A Codes** and **Group B Codes** were used to identify SLD outcome events. In all cases the first occurrence of one of the codes was required to appear among the facility record discharge

diagnoses, and the admission date of the hospitalization with the SLD defining code must have fallen within the *SLD risk period*.

The codes used to define the SLD outcome event (Group A and Group B) originated with a group of definitions previously validated for the Mini-Sentinel Project by V. Lo Re et al.<sup>6</sup> and another set developed by K Arnold Chan et al.<sup>7</sup> The initial list developed from those two sources were reviewed and modified by the ESC and SDL adjudication panel.

**Group A Codes** ([Appendix 8](#)) were considered to usually reflect liver injury / disease and were not required to be a primary discharge diagnosis. Patients were selected for adjudication review if the first occurrence of any of the following codes appeared anywhere among the facility record discharge diagnoses:

**ICD-9-CM Diagnosis Codes**

570 Acute and subacute necrosis of liver  
 572.2 Hepatic coma  
 572.4 Hepatorenal syndrome  
 V42.7 Liver replaced by transplant

**ICD-9-CM Procedures Codes**

50.5 Liver transplant  
 50.51 Auxiliary liver transplant  
 50.59 Other transplant of liver

**CPT® Procedure Codes**

47135 Liver allotransplantation; orthotopic, partial or whole  
47136 Liver allotransplantation; heterotopic, partial or whole

CPT Copyright 2013 American Medical Association. All rights reserved. CPT is a registered trademark of the American Medical Association.

**Group B Codes** ([Appendix 8](#)) were considered highly suspicious indicators of SLD and were required to be a primary facility discharge diagnosis. Patients were selected for adjudication review if the first occurrence of any of the following codes appeared as a primary discharge diagnosis on the facility record:

**ICD-9-CM Diagnosis Codes**

277.4 Disorders of bilirubin excretion  
 571.5 Cirrhosis of liver without mention of alcohol  
 572.8 Other sequelae of chronic liver disease  
 573.0 Chronic passive congestion of liver  
 573.3 Hepatitis, unspecified  
 573.8 Other specified disorders of liver  
 573.9 Unspecified disorder of liver

782.4 Jaundice, unspecified  
 794.8 Non-specific abnormal results of liver function test

#### **ICD-9-CM Procedure Codes**

50.11 Closed (percutaneous) [needle] biopsy of liver  
 50.12 Open biopsy of liver  
 50.13 Transjugular liver biopsy  
 50.14 Laparoscopic liver biopsy  
 50.91 Percutaneous aspiration of liver

#### **CPT® Procedure Codes**

47000 Biopsy of liver, needle; percutaneous  
 47001 Biopsy of liver, needle; done at time of other major procedure  
 47100 Biopsy of liver, wedge  
 78205 Liver imaging (SPECT)  
 78206 Liver imaging (SPECT); with vascular flow

**Appendix 8** provides a flowchart that illustrates the algorithm employed to select patients for SLD adjudication review.

#### **8.4.4.2 Interstitial Lung Disease (ILD) Outcome Event Definition**

Suspected outcomes for the ILD primary analysis were identified using the ILD Narrow definition. The ILD Narrow definition (**Appendix 9**) was based on inpatient ICD-9-CM diagnosis codes described in a systematic review for the FDA's Mini-Sentinel Project by Natalie Jones et al.<sup>8</sup>

For each patient, the first hospitalization with a discharge diagnosis code meeting the ILD Narrow definition within *ILD risk period 1* was identified as the suspect ILD outcome event. The ILD defining diagnosis code could appear anywhere among the facility discharge diagnoses (i.e., it did not have to be the primary discharge diagnosis). The admission date of the hospitalization with the ILD defining code was assigned as the suspect ILD outcome event date.

The ILD Narrow definition outcome codes were:

#### **ILD Narrow Definition - ICD-9-CM Diagnosis Codes**

515 Post-inflammatory pulmonary fibrosis  
 516.3 Idiopathic fibrosing alveolitis

---

Please note that there is limited literature providing administrative and claims data-based definitions / coding algorithms to identify ILD. Although none of the ICD-9-CM codes listed above have been validated, and they may not provide optimum levels of sensitivity and specificity, they were reviewed and approved for use in this study by the Epidemiology Steering Committee and, subsequently, the ILD Adjudication Committee.

[Appendix 9](#) illustrates the process used to select patients during ILD Risk Period 1 based on the ILD Narrow Definition for adjudication review.

## 8.5 IDENTIFICATION OF POSSIBLE CONFOUNDERS/RISK FACTORS

A confounder is a variable that is related to both the exposure and the outcome event of interest. The following variables were identified as potential confounders in the DoD data analysis.

### 8.5.1 SLD Potential Risk Factors / Confounders

- History of Alcoholism;
- History of Bile duct disorders;
- History of Congestive heart failure;
- History of Diabetes;
- History of Obesity;
- Use of other anti-arrhythmic medications (non-study medications);
- Prior use of potentially hepatotoxic medications (systemic use only).

See [Appendix 10](#) for code list definitions.<sup>9</sup>

### 8.5.2 ILD Potential Risk Factors / Confounders

- History of Asthma;
- History of Bronchitis, excluding acute bronchitis;
- History of Chronic obstructive pulmonary disease;
- History of Connective tissue disease;
- History of Exposure to occupational and environmental toxins;
- History of Gastroesophageal reflux disease;
- Use of other anti-arrhythmic medications (non-study medications)

- Prior use of agents associated with drug-induced pulmonary disease, (systemic use only)<sup>10</sup>;
- Prior use of Therapeutic oxygen treatment.

See [Appendix 11](#) for code list definitions.<sup>11</sup>

## 8.6 ADJUDICATION OF OUTCOME EVENTS

Outcome event adjudication involved manual review of patients' medical and prescription histories from the electronic medical records (DOD) and medical claims data (HIRD). Patient histories surrounding the suspected event(s) for patients with occurrences of one or both outcome events (SLD or ILD) were reviewed by the respective IAP. If available, up to one year of patient history preceding the Index Date, and up to six months of history following the outcome event was provided for suspected SLD cases. For suspected ILD events, history up to one year preceding the Index Date and through the end of the patient's follow-up period was provided for IAP review. The data were formatted as patient profiles, with all diagnoses, procedures, drug dispensings, and other available data presented chronologically for IAP members' review.

In order to blind IAP members to all patient-identifying information, profiles were codified with encrypted patient numbers. Dispensing records involving study drugs were *highlighted* in the patient profiles, although IAP members were blinded to the specific study drug exposure (drug name, quantity, and formulation), the dispensing date and the quantity dispensed were provided. Members of the appropriate IAP reviewed each case independently and determined, given the patient records and timing of the outcome event relative to patient's ongoing medical and drug history, whether the suspected outcome event was likely a valid outcome event or confounded by other medical conditions occurring at the same time.

Each IAP member indicated their determination from the list below for each suspected outcome:

- **“Yes”** – the patient profile contains diagnostic/procedural coding that meets the outcome event criteria.
- **“No”** – the patient profile does not have diagnostic/procedural coding that meets the outcome event criteria.
- **“Indeterminate”** – the patient profile does not have diagnostic/ procedural coding that meets the outcome event criteria, but the clinical picture suggests an outcome event may have occurred.

Panel member decisions were tabulated for each outcome event. In cases where panel members' decisions were unanimous, the agreed upon determination was entered for the case in the study database. No further discussion was needed. When panel members disagreed regarding an outcome determination, the patient profile was discussed in a formal meeting where all three IAP

members and the Chair were present. The Chair led the discussion. After each panel member presented and discussed the reasoning for their decision, a final vote was taken. If the final vote was unanimous, or reflected a majority decision (i.e., 2 of the same decision), that decision was assigned to the outcome event in the study database. If each of the three IAP members reached a different conclusion, the outcome event was assigned the value “Indeterminate” in the study database.

## 8.7 BIAS

### Propensity Score Matching

In order to account in the analyses for baseline patient characteristics that are known measureable confounders, propensity score (PS) matching was used to balance those characteristics as much as possible for the final outcomes analyses. Separate propensity score matching was conducted for the SLD, *ILD Narrow definition* and *ILD Broad definition* populations. (See [Section 8.10.2.1](#))

All outcomes analyses were conducted in the PS-matched analysis datasets.

## 8.8 STUDY SIZE

Sample-size requirements for the analyses were estimated based on the following statistical design parameters and assumptions. They are based on the population size prior to propensity score matching.

- **Type of Analysis:** Comparison of event-free “survival” time between the dronedarone-exposed cohort and each comparator (reference) cohort, by means of the log-rank test, or Cox proportional-hazards regression
- **Alpha Level:** 0.05 ( $p \leq 0.05$  considered statistically significant)
- **Power:** 80% (80% chance of obtaining a significant result if a true difference in event-free survival between cohorts exists, and is of an important magnitude)
- **Effect Size of Importance:** Hazard Ratio = 3.0
- **Incidence Rate in the Comparator (Reference) Group:** 1 event/1,000 patient-years
- **Group size Ratio:** 1:1 (equal numbers of dronedarone and comparator subjects), consistent with 1:1 propensity-score matching
- **Accrual Interval:** 5 years (July 2009 through March 2014)
- **Follow-up Beyond Last Accrual:** 6 months (Index Dates ranged from July 2009 through March 2014)

The following chart shows the number of dronedarone subjects required to provide 80% power, at the 0.05 alpha level, to detect hazard ratios of 2.0, 3.0, and 4.0, for various values of the comparator (reference) group incidence rate:

| Incidence Rate (Events / patient-years<br>In the Comparator Group) | # of Subjects Needed<br>in Each Cohort |              |        |
|--------------------------------------------------------------------|----------------------------------------|--------------|--------|
|                                                                    | HR=2.0                                 | HR=3.0       | HR=4.0 |
| 0.01%/year (1 / 10,000 patient-years)                              | 108,947                                | 38,553       | 22,698 |
| 0.02%/year (1 / 5,000 patient-years)                               | 54,477                                 | 19,278       | 11,351 |
| 0.05%/year (1 / 2,000 patient-years)                               | 21,800                                 | 7,714        | 4,542  |
| 0.1%/year (1 / 1,000 patient-years)                                | 10,906                                 | <b>3,860</b> | 2,273  |
| 0.2%/year (1 / 500 patient-years)                                  | 5,460                                  | 1,933        | 1,138  |
| 0.5%/year (1 / 200 patient-years)                                  | 2,192                                  | 776          | 457    |
| 1%/year (1 / 100 patient-years)                                    | 1,103                                  | 391          | 231    |

[Software used to produce calculations: PS - Power and Sample Size Calculations, version 3.0, by W. D. Dupont and W. D. Plummer (Vanderbilt University).]

The incidence rate of 1 per 1,000 patient years was considered a sufficiently conservative estimate to use in the sample size calculations. Therefore, for a hazard ratio (HR) of 3.0, the minimum required sample size was 3,860 patients per study drug cohort.

The *dofetilide* and *propafenone* cohorts did not meet the required sample size of 3,860 patients. They were excluded prior to the propensity score matched process.

Background data to support the sample size and power calculations were provided by Sanofi from a retrospective cohort study conducted internally by the company in 2011. That study used integrated medical and prescription claims data from the LabRx database (Safety Study Report – Dronedarone, SR33589, GPE Pharmacoepidemiology, August 2, 2011). That study found the following:

| Outcome Studied                              | Incidence Rate in dronedarone cohort / 1,000 PYs |
|----------------------------------------------|--------------------------------------------------|
| Incidence of acute liver injury <sup>‡</sup> | 7.6 (0.9 - 14.2)                                 |
| Incidence of interstitial lung disease       | 21.9 (10.5 - 33.4)                               |

<sup>‡</sup> Defined as a primary diagnosis of acute or sub-acute necrosis of liver, hepatic coma, toxic hepatitis, or liver transplant in hospital by ICD-9-CM and CPT codes.

## 8.9 DATA MANAGEMENT AND TRANSFORMATION

An extract of the DoD data meeting requirements specified for the study was provided by HRTx. The de-identified data were made available to Degge as SAS datasets, accessible remotely on a secure site administered by Evolvent / ManTech International Corporation (Evolvent). Degge staff applied screening criteria to identify cases meeting eligibility requirements for the analyses, generated summary baseline variables and identified relevant outcomes to create analysis datasets on the Evolvent site using SAS 9.2 (Cary, NC). The analysis datasets were accessed by Degge's end users where descriptive tables were produced and analyses conducted using SAS 9.4 (Cary, NC).

## 8.10 STATISTICAL METHODS

### 8.10.1 Main summary measures

Selected baseline and post-Index Date characteristics are summarized in tabular format for patients in each outcome study population prior to PS matching, as well as for patients in the respective propensity score matched analysis datasets. General categories of reported characteristics include demographics (age, gender and race), baseline history of diseases relevant to each outcome of interest, and baseline use of medications relevant to each outcome of interest.

In addition to baseline characteristics, patient follow-up time, length of index treatment episode, and number of non-index study drugs dispensed after the Index Date are summarized for all pre- and post-PS-matched datasets.

Summary descriptive data are reported as either mean values (e.g., Deyo-Charlson Index) or proportions (e.g., distribution by race).

Data were also tabulated to show person-years of exposure and number of events during the relevant risk period, by cohort, for each outcome (i.e., SLD and ILD). Incidence rates per 1,000 person-years of exposure (SLD) or follow-up (ILD) and accompanying 95% confidence intervals (CI) were then calculated for each outcome. The log-rank (Mantel-Haenszel) test was used to test the significance of differences in incidence rates between the dronedarone cohort and each comparator cohort. Cox Proportional Hazards (CPH) modeling was conducted to compare event rates over time, between cohorts, with dronedarone as the referent study drug. The HR, 95% CI and p-value of the results are presented for each analysis.

### 8.10.2 Main statistical methods

#### 8.10.2.1 Propensity Score Matching

Dronedarone is the newest of the anti-arrhythmics considered in this study, and there are likely factors that influenced physicians' decisions to initiate treatment with this drug (as well as decisions to treat with the other study drugs). In order to account in the analyses for potential patient characteristics that are known measurable confounders (i.e., they may influence the decision to initiate treatment on a particular drug, and also affect patient outcomes) PS matching was used to balance, as much as possible, those baseline characteristics. Separate PS matching was conducted for the SLD, *ILD Narrow definition* and *ILD Broad definition* populations. Patients in each of the three comparator cohorts meeting the size requirement (i.e., amiodarone, sotalol and flecainide) were PS matched to patients in the dronedarone cohort. The PS matching process is described below in more detail.

#### **8.10.2.2 Propensity Score Matching Procedure**

Propensity score matching (PSM) is a statistical technique that attempts to isolate the estimated effect of a treatment or exposure by accounting for the covariates that predict the likelihood of the exposure. PSM employs a predicted probability of exposure based on observed predictors, usually obtained from logistic regression. The technique provides a close adjustment for differences in covariates at baseline and thereby reduces bias due to confounding variables that could be found in an estimate of the exposure effect obtained from simply comparing outcomes among exposed subjects (in this case, the dronedarone cohort) versus unexposed subjects (the comparator cohorts).

An attempt was made to match one patient from each of the three comparator cohorts amiodarone, sotalol, and flecainide to each patient in the dronedarone cohort according to PS. The matching was conducted without replacement. Specifically, three separate subsets of the DoD database, each containing all of the dronedarone patients and patients from one of the comparator cohorts were created. The same reduced logistic regression model (derived from the dataset combining all cohorts) was independently fitted to each of the subsets and the results used to calculate a PS for each patient in the subset. Within each subset, the absolute difference between PS scores for each dronedarone and comparator patient was calculated. Selecting dronedarone patients in random order, and employing a caliper of 0.2 (i.e., the maximum allowable difference between treatment and control PS scores was 0.2 X the standard deviation of the mean propensity score for data comprised of the dronedarone patients plus the comparator cohort being matched), the closest patient in each comparator cohort was selected for matching (from remaining comparators not already matched to another dronedarone patient). If matches for a given dronedarone subject were not found across all comparator groups then the dronedarone subject was considered unmatchable and excluded from the analysis. (See

**Appendix 12 – Figure 1)**

PS matching generated a dataset of patients whose baseline covariate distributions were nearly identical across the four cohorts. This allowed for comparison of outcomes between dronedarone users and comparator cohorts using transparent, simpler unmatched methods that do not require explicit adjustments for individual confounders. Multiple variations of PS models and matching schema were tested in order to find the best match of baseline characteristics. In the event that one or more variables remained severely unbalanced between the amiodarone cohort and one or more of the PS-matched comparator groups after PS matching (see section 8.10.2.6), an explicit adjustment for the severely unbalanced confounder(s) was included as a covariate in the relevant CPH model.

#### **8.10.2.3 Evaluation of Propensity Score Model and Matching**

The adequacy of PS-based matching was assessed in several ways:

- The goodness of fit of the logistic model was examined using the Lemeshow<sup>12</sup> test for calibration and by the C-statistic for discrimination.
- The choice of caliper width was justified by sensitivity analysis of a range of caliper widths, demonstrating that the chosen width (0.2) strikes an acceptable balance between number of potential matches and closeness of the match (described below).
- Standardized differences were used to compare baseline values of the potential confounders between the PS-matched dronedarone cohort and each of the PS-matched comparator cohorts to ensure balance across the cohorts.
- Survival analyses were conducted for groups stratified by PS-quintile, and also by including PS as a covariate in the Cox proportional hazards regression analyses. These sensitivity analyses ruled out any potential systematic differences in results by PS score.

#### **8.10.2.4 Fit of the Logistic Model**

The adequacy of the logistic model to represent the dependence of dronedarone exposure on the baseline values of the available potential confounders was checked in several ways.

- The fit was evaluated graphically. All records were sorted by PS and a graph was generated of the cumulative sum of the PS values (y), versus the corresponding cumulative fraction of subjects who were actually in the exposed category (x). If the data actually conformed to the fitted logistic model, the plotted points would lie exactly along a straight diagonal line between (0,0) and (1,1).
- The adequacy of the logistic fit was also evaluated by the Lemeshow test for calibration and by the C statistic for discrimination.

#### **8.10.2.5 Effect of Caliper Width**

The log-odds of the probability calculated by the reduced logistic regression model was used as the PS. (The log-odds is the linear portion of the logistic model, prior to transformation into a probability.) Caliper width for nearest-neighbor matching was based on a fraction of the standard deviation of the PS. Several caliper-width strategies were evaluated, and a choice made so as to achieve an acceptable tradeoff between poor matching (caliper too wide) and excessive exclusion of patients from the matched population (caliper too narrow).

#### **8.10.2.6 Balance of Baseline Values between Matched Cohorts**

Tables summarizing baseline measures of potential confounders for patients in each of the cohorts retained for the analyses were generated both before and after PS matching (means and standard deviations for continuous variables; numbers and proportions for dichotomous variables). Standardized differences were calculated to compare the balance of baseline confounder values between the dronedarone patients and patients in each comparator cohort. Confounders were considered well balanced if the value of the standardized difference was 10% or less. Confounders with standardized differences >25% were considered severely unbalanced.

#### **8.10.2.7 Variability of Hazard Ratios with PS for the Primary Outcome**

Unlike randomization, which (in the long run) will compensate for the effects of all known and unknown confounders between groups, PS matching can hope to compensate only for known confounders that were included in the PS model. Therefore, even in a study where PS matching has been executed perfectly, and the cohorts are completely balanced for all known confounders, the outcome event can be affected by unknown confounders that remain unbalanced between cohorts. This is an intrinsic limitation of PS matching. It has been tested for in two ways:

- Running analyses for groups of patients stratified by PS-based quintiles, and checking whether the outcomes vary systematically across the sequenced strata.
- Incorporating the PS as a covariate (with interaction terms between PS and the cohorts), and checking whether the coefficients of the interaction terms are significantly different from zero.

If PS-dependence of outcomes were observed, it would mean that the effect of a comparator drug on the outcome, relative to dronedarone, could be biased by the unknown (and uncompensated) confounders. Results would therefore need to be interpreted with caution.

#### **8.10.2.8 Survival Analyses**

#### **8.10.2.8.1      *Cox proportional-hazards regression analysis***

Separate CPH<sup>13</sup> modeling was to be carried out for each outcome, although as adjudication found no true cases of SLD this analysis was only conducted for the ILD outcome. The CPH model used exposure group (dronedarone as the reference drug) as the main independent variable, and incorporated as explicit covariates the confounders that remained severely unbalanced after propensity score matching. Results have been presented as either crude or adjusted hazard ratios (depending on whether or not unbalanced covariates were included in the model), with 95% confidence intervals and p-values, for each comparator drug relative to dronedarone.

For all models, the Schoenfeld residual test was performed to test the proportionality assumption.<sup>14</sup>

#### **8.10.2.8.2      *Kaplan Meier Survival Estimates***

Graphs displaying separate Kaplan-Meier survival curves for each exposure group were prepared for the ILD outcome.<sup>15</sup> The log-rank test was performed to identify any statistically significant difference between the dronedarone versus comparator drug cohort curves. Like the CPH analysis, Kaplan-Meier curves were not generated for the SLD outcome as no cases were adjudicated as true SLD.

### **8.10.3      Missing values**

Missing values relating to the study outcomes were not encountered. Patient records with missing data, e.g., demographics and comorbid conditions were not observed.

### **8.10.4      Sensitivity analyses**

#### **8.10.4.1      *Addition of Laboratory Data to SLD***

A sensitivity analysis of SLD outcomes was conducted by re-adjudicating cases with the addition of laboratory test results (e.g., alanine transaminase levels, aspartate transaminase levels, bilirubin levels), where available. The goal of this sensitivity analysis was to determine: 1) if those cases are representative of the database population, and 2) if the laboratory information adds value to the existing data.

#### **8.10.4.2      *ILD Sensitivity Analyses***

Three sensitivity analyses were conducted for the ILD outcome by varying the outcome definition (Narrow versus Broad) and risk period (Follow-up period (Risk Period 1) versus Index Treatment Episode (Risk Period 2)).

### 8.10.5 Amendments to the statistical analysis plan

The statistical analysis plan was carried out as planned.

## 8.11 QUALITY CONTROL

Degge implements quality control procedures to verify data analyses. Those include review of programming and results by a second programmer and review of all report tables for reasonable values and consistent totals. Also, the study was conducted in accordance with Guidelines for Good Pharmacoepidemiology Practice established by the International Society of Pharmacoepidemiology and Therapeutic Risk Management.<sup>16</sup>

## 9. RESULTS

A total of 146,333 patients with a new prescription for one of the study drugs of interest dispensed between 20 July 2009 and 31 March 2014 were identified in the DoD database. Patients were assigned to study drug cohorts on the basis of their earliest pharmacy record, dated on or after 20 July 2009, showing one of the study drugs dispensed. **Table 1** shows patient attrition associated with application of each of the initial screening criteria, as described in **Sections 8.3.2** and **8.3.3**. Following the initial screening 51,391 patients remained in the *Final study drug cohorts*. Figure 2 graphically describes the initial screening process.

Patient characteristics and results of outcome analyses are described in the sections that follow, separately for the SLD and ILD analyses. Results of the three ILD sensitivity analyses are provided separately in **Appendix 13**.

**Table 1. Number of Patients with a Study Drug of Interest between 20 July 2009 and 31 March 2014 by Study Drug Cohort and Screening Criteria: DoD Database - 20 July 2009 through 30 September 2014**

| Baseline Exclusionary Screening Description                       | Dronedarone  |             | Amiodarone    |             | Sotalol      |             | Flecainide   |             | Dofetilide |             | Propafenone  |             |
|-------------------------------------------------------------------|--------------|-------------|---------------|-------------|--------------|-------------|--------------|-------------|------------|-------------|--------------|-------------|

\* Patients with multiple study drugs on the same Index Date were not considered for inclusion in the study.

† Additional screening to reflect Epidemiology Study Protocol.

‡ Includes SLD, viral hepatitis, and hereditary conditions.

§ Includes ILD, pneumonia, and sarcoidosis.

**Figure 2. Identification and Initial Selection Screening to Identify the Study Drug Cohorts; US DOD Database: 20 July 2009 to 30 September 2014**

## 9.1 SLD PATIENT RESULTS

The *SLD study population* was created from the *Final study drug cohorts* by removing those with baseline occurrences of SLD. Following the additional screening, 47,672 patients were retained for the *SLD study population* (see Figure 3).

**Figure 3. SLD Outcome Screening to create the SLD Study Populations; US DOD Database: 20 July 2009 to 30 September 2014**

## 9.1.1 SLD Descriptive data

### 9.1.1.1 Characteristics of Patients in the SLD Study Population Prior to Propensity Score Matching

#### 9.1.1.1.1 Baseline characteristics

**Table 2** presents baseline demographic characteristics, disease and medication use histories for all patients meeting the *SLD study population* inclusion criteria.

Amiodarone users comprised the largest study drug cohort in the *SLD study population*, with more than double the number of patients found in the second largest cohort (n=22,908 versus n=8,821 in the dronedarone cohort).

The propafenone and dofetilide cohorts were the smallest in the *SLD study population*. Both failed to meet the required minimum 3,860 patients (n=3,329 and n=858, respectively), and thus were excluded from the SLD outcome analysis.

#### 9.1.1.1.2 Demographic characteristics

Age varied across study drug cohorts, with the flecainide and propafenone cohorts having relatively younger patients (mean age 64.2 and 67.7 years, respectively) and the amiodarone cohort having the oldest patients, on average (mean age 73.8 years).

Patient distribution by gender also varied across cohorts. Females constituted only about one-third of patients in the dofetilide cohort (34.5%) compared to roughly half the propafenone, flecainide, sotalol, and dronedarone users (51.9%, 50.2%, 47.0%, and 46.9%, respectively).

Race was unknown for more than half the patients in each cohort. In all cohorts, between 84% and 89% of patients with known race were White. No other single racial group accounted for more than 8% of patients with known race in any cohort.

#### 9.1.1.1.3 History of Disease

Patients in the *SLD study population* had relatively low Scores on the Deyo-Charlson Index (DCI), although there was notable variation by cohort. The lowest mean DCI of 0.84 was found in the youngest cohort (flecainide), and the highest (2.2) in the oldest cohort (amiodarone).

**Table 2)**

Differences were also noted in baseline prevalence of the specific diseases reported in **Table 2**.

Congestive heart failure (CHF) appeared in the baseline diagnoses of roughly half the amiodarone and dofetilide patients in the *SLD study population* (52.1% and 44.6%, respectively). In contrast, only 11.6% of patients in the flecainide cohort had baseline CHF diagnoses.

Baseline prevalence of diabetes was also highest in the amiodarone cohort (41.4%). Roughly one third of dofetilide, sotalol and dronedarone patients had a history of diabetes (34.8%, 34.0%, and 32.6%, respectively) and one fifth (19.9%) of the flecainide cohort had baseline records indicating this condition.

Diagnoses identifying baseline obesity were found for between 15% and 16% of patients in five of the study drug cohorts. The exception was the dofetilide group, in which nearly one fourth the patients (23.9%) had baseline obesity. Since BMI measurements are not consistently available in this database, it is possible that obesity diagnoses may be more prevalent in the *SLD study population* than is apparent from observing diagnoses alone.

At most 5% of patients in any cohort had diagnoses suggestive of bile duct disorders in the twelve months preceding their Index Date. Alcoholism diagnoses were also rare. Only 38 patients in the entire study population had baseline diagnoses representing a history of alcoholism, accounting for 0.12% or less of patients in any single cohort; however. As with obesity, alcoholism may be underreported in the MHS.

#### **9.1.1.1.4 History of Medication Use**

Roughly one half to two thirds of the *SLD study population* had claims during the baseline period for potentially hepatotoxic medications. Acetaminophen (or combination drugs including acetaminophen) was the single most common of the potentially hepatotoxic drugs, found in baseline records of 38.9% of the *SLD study population*. In addition to the commonly used acetaminophen combinations, the list of top five most common potentially hepatotoxic drugs in the *SLD Study population*, and proportions of patients dispensed the drugs at least once in the baseline period, were ciprofloxacin HCL (12.2%), amoxicillin-potassium/clavulanate (8.0%), allopurinol (5.2%), and fenofibrate (5.1%). Patients with these exposures were not excluded from the study population, and their use in the temporal profiles was reviewed by the adjudicators in making their assessments.

Few patients had dispensing records for other anti-arrhythmic agents (0.6% or less of cohort members).

#### **9.1.1.1.5 Post-Index Date Characteristics - SLD Study Population Patient Follow-Up Time**

Follow-up time for patients in the *SLD study population* is summarized in [Table 3](#). The average length of follow-up ranged from 865 days (roughly 29 months) to 1,080 days (roughly 36 months) for all cohorts, with the amiodarone cohort having the shortest follow-up time, and dronedarone the longest.

Corresponding to its shorter average follow-up, the amiodarone cohort had the highest proportion of patients whose follow-up lasted one year or less (22.0% versus 10.6% to 14.5% in other cohorts). In contrast, nearly three-fourths of the dronedarone cohort (72.6%) had more than two years of follow-up, compared to between 54.6% and 68.8% with a follow-up longer than two years among the other study drug cohorts.

#### **9.1.1.1.6 Post-Index Date Characteristics - Index Treatment Episode**

Most patients in the *SLD study population* had one year or less of exposure in the index treatment episode. ([Table 4](#)) The mean length of patients' index treatment episodes ranged from a low of 201 days (approximately seven months) in the amiodarone cohort, to a high of 459 days (approximately 15 months) in the dofetilide cohort. Dronedarone users' mean index treatment episode duration was 341 days (approximately 11 months).

#### **9.1.1.1.7 Non-Index Study Drugs Dispensed**

[Table 4](#) also shows the distribution of patients, by cohort, according to numbers of non-index study drugs dispensed during the follow-up period. Most patients in the *SLD study population* had no record of having been dispensed a study drug, other than their index drug, during the

interval. The amiodarone cohort had, by far, the highest percentage of patients with no other study drug (90.2%). At most, one-third of patients in the dronedarone and propafenone cohorts were dispensed at least one study drug other than the one received on their Index Date. Most of those patients (27.2% and 24.8% of all dronedarone and propafenone patients, respectively) were dispensed only one non-index study drug.

<sup>a</sup> Length of index treatment episode is calculated as time from Index Date to the end of the index treatment episode.

#### **9.1.1.2 Characteristics of Patients in the SLD PS-matched Analysis Dataset**

The SLD outcome analysis was conducted in the subset of PS-matched patients from the four cohorts in the *SLD Study Population* meeting the minimum size requirement for the study power calculations. That subset is referred to as the *SLD analysis dataset* and consisted of equal numbers of patients from the dronedarone, amiodarone, sotalol and flecainide cohorts (n=4,123 each; total n=16,492). **Table 5** summarizes patient characteristics both before and after PS matching, including standardized differences calculated to compare the dronedarone cohort separately to each of the three comparator cohorts. Standardized differences exceeding a value of 25 (representing a difference of more than 25% of the pooled standard deviation of the compared values) were considered significant in these analyses. **Table 6** summarizes baseline demographic characteristics and selected baseline history of disease and medication use for the PS-matched cohorts.

**Table 5. Standardized Differences in PS Model Covariates between Dronedarone and Comparator Cohorts for SLD Population vs. SLD Analysis Dataset Before and After Propensity Score Matching: DoD Database - 20 July 2009 to 30 September 2014**

### 9.1.1.2.1 Baseline characteristics

#### 9.1.1.2.1.1 Demographic Characteristics

Most demographic characteristics were well balanced between the dronedarone cohort and each of the three PS-matched comparator cohorts in the *SLD analysis dataset*. Prior to PS matching, significant differences between the dronedarone cohort and one or more of the comparator cohorts were found for six baseline patient characteristics (age, study year of Index Date, congestive heart failure, diabetes, hospitalization, and mean number of different medications). In

the matched data only age, study year of Index Date and congestive heart failure remained unbalanced. After PS-matching mean age and congestive heart failure were both unbalanced between the dronedarone cohort and sotalol cohorts. Age and study year of Index Date remained unbalanced only between the dronedarone and amiodarone cohorts (**Table 5**). Potential confounders remaining unbalanced after PS-matching were explicitly controlled for in the CPH regression used to compare the risk of SLD over time between dronedarone and the relevant comparator cohorts.

With the exception of the flecainide cohort, mean age in the *SLD analysis dataset* was generally lower than in the study population prior to propensity score matching, ranging from 67.3 in the flecainide cohort to 70.5 in the amiodarone and sotalol cohorts. As seen in **Table 5**, mean age was severely unbalanced between the dronedarone cohort and both the amiodarone and flecainide cohorts prior to PS matching (70.4 years mean age for dronedarone versus 73.8 years for amiodarone and 64.2 years for flecainide, standardized difference=36.4 and 53.6, respectively). After matching, mean age was severely unbalanced between the dronedarone cohort and the amiodarone and sotalol cohorts (67.8 years mean age for dronedarone versus 70.5 years for both the amiodarone and sotalol cohorts, standardized difference=25.9 and 26.0, respectively). Mean age of the flecainide cohort was roughly the same as that of the dronedarone cohort in the matched dataset (67.3 years).

The PS-matched data were well balanced by gender, with females comprising roughly half of each cohort (range 47.9% to 50.5%).

Race was unknown for more than half the patients in each PS-matched cohort (range 56.8% to 65.7%). Among patients with known race, between 85% and 88% of each cohort were White. Blacks accounted for about 6% to 7% of patients with known race. The combined group of Asians/Pacific Islanders, American Indian/Alaskan natives, biracial patients, and those reporting Other race accounted for the remaining 6% to 8% of patients with non-missing race in each cohort.

#### **9.1.1.2.1.2 History of Disease**

After PS-matching the mean DCI was lower among patients in the dronedarone, amiodarone and sotalol cohorts (1.1, 1.5 and 1.4, respectively). (**Table 6**) Like the overall *SLD study population*, the amiodarone cohort still had the highest value on this measure of morbidity. In the flecainide cohort, which had the lowest DCI prior to PS-matching, the value in the matched cohort was slightly higher (1.0 vs. 0.84).

The change from pre- to post-PS matching in the proportion of patients with baseline CHF was most dramatic in the dronedarone and amiodarone cohorts, where the percentages dropped by

roughly one-half and two-thirds from the corresponding values prior to PS matching (to 14.1% and 19.8%, respectively). Baseline CHF was also notably lower in the PS-matched analysis population for the sotalol cohort (25.6%), although slightly higher in the flecainide cohort (13.9%). While proportions of dronedarone versus amiodarone and flecainide patients with CHF were severely unbalanced in the overall *SLD study population*, only the proportions of dronedarone versus sotalol patients were severely unbalanced after PS matching. (**Table 5**)

Diabetes remained a highly prevalent baseline condition in the PS-matched cohorts, although the proportions were more similar across cohorts than in the overall *SLD study population* and lower in all but the flecainide cohort. Roughly one-fourth of the PS-matched dronedarone and flecainide cohorts (23.6% and 22.9%, respectively), and one-third of the amiodarone and sotalol cohorts (30.7% and 32.4%, respectively) had indications of diabetes in the matched dataset. Absolute percentage changes in proportion of patients with the condition were greatest in the amiodarone and dronedarone cohorts (41.4% versus 30.7%, and 32.6% versus 23.6% pre- to post-matching, respectively). (**Table 5, Table 6**)

The proportions of patients with obesity diagnoses in the PS-matched data were similar across cohorts, albeit slightly lower than in the overall population (15.5%, 15.4%, 15.3% and 15.8% for the PS-matched dronedarone, amiodarone, sotalol and flecainide cohorts, respectively). (**Table 5, Table 6**)

Bile duct disorders, which were rare in the overall *SLD study population* (less than 5% of any cohort), appeared even less frequently in all but the flecainide cohort after PS-matching. The proportions of patients with diagnoses indicative of bile duct disorders during the 365 days prior to and including their Index Date ranged from 2.2% to 2.8% in the *SLD analysis dataset*. (**Table 6**)

Baseline alcoholism diagnoses, extremely rare prior to PS-matching, were found in records of a total 13 patients in the entire *SLD analysis dataset*. With five patients, the flecainide cohort had the highest number of diagnoses indicating a history of alcoholism in the baseline period. The PS-matched dronedarone, amiodarone, and sotalol cohorts had only two or three patients each with alcoholism. (**Table 6**)

#### **9.1.1.2.1.3 History of Medication Use**

After PS matching, the proportions of patient records identifying baseline use of other anti-arrhythmic agents were equally low in all cohorts, as was seen in the pre-matched data. All cohorts in the *SLD analysis dataset* had roughly 0.4% of patients with pharmacy records for other anti-arrhythmics dispensed. (**Table 5, Table 6**)

Similarly, proportions of patients dispensed potentially hepatotoxic drugs in the baseline period were balanced across cohorts within each of the two datasets. Between 58% and 62% of patients

in the four *SLD analysis dataset* cohorts were dispensed at least one of these drugs during the baseline period. (**Table 6**) The five potentially hepatotoxic drugs dispensed to the highest proportions of patients in the *SLD analysis dataset* were acetaminophen / combination products containing acetaminophen (38.0%), ciprofloxacin (12.7%), amoxicillin-potassium clavulanate (8.2%), diclofenac (5.4%) and fenofibrate (5.1%).

#### 9.1.1.2.2 Post-Index Date Characteristics - Index Treatment Episode

The length of index treatment episodes for patients in the *SLD analysis dataset* is summarized in **Table 7**. The average length of index treatment episode for patients in the analysis dataset ranged from 210 to 391 days by cohort (roughly 7-13 months). The maximum difference of roughly one half year was between the amiodarone and sotalol cohorts.

**Table 7. SLD Analysis Dataset Length of Index Treatment Episode according to Study Drug Cohort: DoD Database - 20 July 2009 through 30 September 2014**

| Follow-up Time <sup>a</sup> | Dronedarone  |            | Amiodarone   |            | Sotalol      |            | Flecainide   |            |

| Max                         | 1,886        |            | 1,824        |            | 1,891        |            | 1,898        |            |

<sup>a</sup> Length of index treatment episode is calculated as time from Index Date to the end of the index treatment episode.

### 9.1.2 SLD Outcome Events

SLD outcomes were defined by designated diagnosis and/or procedure codes found in records of hospitalizations with admission dates during patients' index treatment episodes. At least one diagnosis designated as potentially indicative of SLD was identified during the index treatment episode for 32 cases in the *SLD analysis dataset*.

The SLD-IAP members independently reviewed the electronic record profile of each suspected case of SLD to determine the validity of the SLD outcome event. Reviewers were blinded to the identification of the study drugs although they were noted in the profiles. All but one of the 32 cases were adjudicated as "No" (i.e., determined not to be valid SLD outcome events), and one

of the cases was adjudicated as “Indeterminate” (i.e., there was not enough information available to make a definitive decision as to whether or not it was a valid SLD outcome event). (**Table 8**)

**Table 8: SLD Analysis Dataset Numbers and Characteristics of Patients with Adjudicated Serious Liver Injury/Disease Events according to Study Drug Cohort: DOD Database - 20 July 2009 to 30 September 2014**

| Indeterminate                              | 0                              | 0.0      | 0                             | 0.0      | 0                          | 0.0      | 1                             | 14.3     |

**Table 9** provides results of the SLD outcome analysis. Total person-years at risk for this analysis were calculated as the sum of days across all patients’ index treatment episodes, within each cohort. A bootstrap method was used to calculate upper confidence intervals for the incidence rates of 0 (zero) cases. Those calculations indicated that, at most, between 1.2 and 2.2 cases of SLD might be expected in a population similar to the one analyzed for this report. No hazard ratio analyses were conducted for the SLD outcome.

<sup>a</sup> Person-years of exposure is the sum of total days in index treatment episodes of all patients in a cohort.

### 9.1.2.1 Other analyses

A planned sensitivity analysis was conducted by re-adjudicating cases with the addition of laboratory data. Only two cases with laboratory data available were found among the 32 with

potential SLD, and the adjudication panel maintained its position that the cases did not meet the definition of SLD as defined in the protocol.

## 9.2 ILD NARROW DEFINITION PATIENT RESULTS

### 9.2.1 ILD Narrow Definition Participants

Patients retained after initial screening of the DoD population were further screened to create the *ILD Narrow Definition study population*. Patients with baseline occurrences of ILD, according to the narrow definition used in the study, were removed from the *Final study drug cohorts* to create the *ILD Narrow Definition study population*. A total of 41,591 patients were included in the *ILD Narrow Definition study population* (see Figure 4).

**Figure 4. ILD Outcome Screening to create the ILD Study Populations; US DOD Database: 20 July 2009 to 30 September 2014**

### 9.2.2 ILD Descriptive data

#### 9.2.2.1 Characteristics of Patients in the ILD Narrow Definition Study Population Prior to Propensity Score Matching

#### **9.2.2.1.1 Baseline characteristics**

Baseline demographic characteristics, and medical and medication use histories for all patients meeting the *ILD Narrow Definition study population* inclusion criteria are found in [Table 10](#). Patients with amiodarone as their first study drug exposure on or after the study start comprised the single largest cohort in this population (n=18,521), followed by users of dronedarone (n=8,128), sotalol (n=6,140) and flecainide (4,915). Neither the propafenone nor dofetilide group had adequate numbers of patients to include in the outcome analysis (n=3,092 and n=759, respectively).

##### **9.2.2.1.1.1 Demographic characteristics**

Mean age ranged from 63.7 years to 73.2 years in the *ILD Narrow Definition study population* cohorts. Patients in the flecainide and propafenone cohorts were younger, on average (mean ages 63.7 and 67.1 years, respectively) compared to members of the other study drug cohorts. The oldest patients, on average, were found in the amiodarone cohort.

With regard to gender, females accounted for roughly half the propafenone, flecainide, sotalol, and dronedarone users (51.2%, 49.5%, 46.9%, and 46.5%, respectively). The dofetilide and amiodarone groups were less evenly balanced by gender, with females comprising only 33.6% and 40% of patients in those cohorts, respectively.

Race was unknown for more than half the patients in each *ILD Narrow Definition study population* cohort. The majority of patients with known race were White (between 84% and 88% of each cohort). No other single group accounted for more than 8% of patients with known race in any cohort.

##### **9.2.2.1.1.2 History of Disease**

Mean DCI scores in the *ILD Study population* ranged from 0.8 to 2.0. The flecainide cohort had the smallest average number of comorbidities by this measure, while the relatively older amiodarone cohort had the highest mean DCI. ([Table 10](#))

**Table 10: Baseline Characteristics of Patients in the ILD Narrow Definition Study Population according to Study Drug Cohort: DOD Database - 20 July 2009 to 30 September 2014**

| Characteristics, N %                           | Dronedarone  |            | Amiodarone    |            | Sotalol      |            | Flecainide   |            | Dofetilide |            | Propafenone  |            |

Gastroesophageal reflux disease (GERD) was the most prevalent of the medical conditions considered in the *ILD Study population*. The proportions of patients with diagnoses for this condition were fairly consistent across study drug groups, appearing in 26% - 31% of patient baseline records by cohort. The lowest prevalence was found in the flecainide cohort, and the highest in the dofetilide cohort.

Chronic obstructive pulmonary disease (COPD) was the second most frequently found condition in all but one of the ILD cohorts. Nearly one fourth (23.5%) of the amiodarone cohort, one fifth (19.6%) of the dofetilide cohort, roughly 17% of dronedarone and sotalol patients and 13.1% of propafenone patients were found to have this diagnosis. COPD appeared much less frequently in the flecainide cohort (8.9%), where it was the third most common of the reviewed conditions.

Roughly 10% of patients in all cohorts had asthma diagnoses, and bronchitis appeared in records of 7%-12% of patients. The other medical conditions investigated (connective tissue disease and exposure to toxins) were found in 4% or less of patient records for any cohort.

#### **9.2.2.1.1.3 History of Medication Use**

Agents known to be potentially associated with pulmonary disease appeared in baseline dispensing records of most patients in the study cohorts. The highest proportions of patients with history of these drugs were found in the amiodarone and dofetilide cohorts (95.2% and 94.2%, respectively).

Grouping agents potentially associated with pulmonary disease into broad categories showed the most commonly dispensed were beta-blockers, found in the baseline records of 35.3% of the *ILD Narrow Definition study population*. More than one fourth of the population were dispensed anticoagulants (28.5%), and another fifth had filled ACE inhibitor prescriptions. Completing the list of five most commonly dispensed drugs potentially associated with pulmonary disease were hydrochlorothiazide (or combination products containing hydrochlorothiazide) and nitrofurantoin, appearing respectively in baseline records of 11.4% and 2.2% of the group.

Less than 1% of patients in any cohort had records indicating baseline use of other anti-arrhythmic agents, and a total of five patients had therapeutic oxygen treatments in the baseline period (3 dronedarone, 1 amiodarone and 1 sotalol patients, respectively).

#### **9.2.2.1.2 Post-Index Date Characteristics - Patient Follow-Up Time**

The follow-up period for patients in the *ILD Narrow Definition study population* began on the day after their Index Date and continued through the earliest occurrence of an ILD outcome

event, end of eligibility in the health plan, death, or the end of the study period (i.e., 30 September 2014). Follow-up time for this population is summarized in [Table 11](#).

The average length of follow-up was between 29.9 months and 36.6 months, with the shortest and longest follow-up periods corresponding respectively to the amiodarone and dronedarone cohorts.

#### **9.2.2.1.3 Post-Index Date Characteristics - Index Treatment Episode**

As reported in [Table 12](#), mean length of index treatment episodes in the *ILD Narrow Definition study population* ranged from 202 days (roughly seven months) in the amiodarone cohort, to a high of 450 days (15 months) in the dofetilide cohort. The longest continuous index treatment episodes lasted for approximately five years in all cohorts.

<sup>a</sup> Length of index treatment episode is calculated as time from Index Date to the end of the index treatment episode.

#### **9.2.2.1.4 Number of Index Drug Treatment Episodes**

As potential ILD outcomes were identified through the end of the follow-up period for the ILD primary analysis, counts of all individual index drug treatment episodes during the follow-up period, by cohort, are reported in [Table 13](#). On average, patients in the *ILD Narrow Definition study population* cohorts had between one and two episodes of treatment with their index drug during the follow-up period, with roughly two-thirds of patients in all cohorts found to have only one treatment episode (minimum 62.4% of the flecainide cohort, to maximum 68.8% of the dronedarone cohort). At most, patients had between 10 and 19 individual index drug treatment episodes by cohort.

#### **9.2.2.1.5 Non-Index Study Drugs Dispensed**

Most patients in the *ILD Narrow Definition study population* had no record of having been dispensed a study drug, other than their index drug, during the interval following their Index Date. ([Table 13](#)) The dronedarone and propafenone cohorts had the highest percentages of patients dispensed at least one prescription for a non-index study drug (33.8% and 33.2%, respectively). Only 11% of the amiodarone cohort had records of at least one other study drug dispensed during the follow-up period.

#### **9.2.2.2 Characteristics of Patients in the ILD Narrow Definition PS-matched Analysis Dataset**

Following the ILD outcome specific screening, three comparator cohorts had the minimum required number of cases for inclusion in the PS-matched *ILD Narrow Definition analysis dataset*. Those were the amiodarone, sotalol and flecainide cohorts. The four cohorts had 4,087 patients each, for a total of 16,348 patients. Standardized differences comparing dronedarone patient characteristics versus each of the comparator cohorts, both before and after PS matching, are found in [Table 14](#). Baseline demographic characteristics and selected baseline disease and medication use history for the PS-matched cohorts are summarized in [Table 15](#).

### 9.2.2.2.1 Baseline characteristics

#### 9.2.2.2.1.1 Demographic Characteristics

Four patient characteristics were severely unbalanced between dronedarone and at least one other cohort prior to PS matching. Those were mean age on Index Date, mean study year of Index Date, hospitalized in baseline, and number of different medications dispensed in baseline. After PS matching, only mean age on Index Date and mean study year of Index Date were still severely unbalanced between the dronedarone cohort and one of the comparator groups. (Table 14)

Mean age in the PS-matched *ILD Narrow Definition analysis dataset* is lower than in the *ILD Narrow Definition study population* among dronedarone, amiodarone and sotalol patients (range 66.7 years to 70.0 years, after PS-matching), and higher in the flecainide cohort (66.7 years after PS-matching). Only the difference between the dronedarone and sotalol cohorts was severely unbalanced after the PS matching (standardized difference=26.7).

The mean study year of patient's Index Date was higher and severely unbalanced in both the amiodarone and flecainide cohorts compared to the dronedarone cohort prior to PS matching. After matching the mean study year of patient's Index Date was still severely unbalanced between the dronedarone and amiodarone cohorts, although the direction of the difference was reversed (standardized difference=26.9). The dronedarone and flecainide cohorts, however, were not severely unbalanced after PS matching.

Prior to PS matching, proportions of patients with at least one baseline hospitalization were notably higher in the amiodarone and sotalol cohorts than in the dronedarone cohort, and the respective standardized differences indicated severe unbalance. Those differences were diminished after PS matching.

Flecainide patients, on average, filled prescriptions for fewer different medications in the baseline than did dronedarone patients in both the *ILD Narrow Definition study population* and the *ILD Narrow Definition analysis dataset*. However, while that difference indicated severe unbalance between the two cohorts for that measure prior to PS matching it was well balanced after PS-matching (standardized difference=36.1 prior to PS matching versus standardized difference=2.3 after PS matching).

Other demographic characteristics were distributed similarly in the pre- and post-PS-matched data.

#### 9.2.2.2.1.2 History of Disease

With regard to number of comorbidities after PS-matching, mean DCI was lower among patients in the dronedarone and amiodarone cohorts (1.1 and 1.6, respectively) and the same or slightly higher in the sotalol and flecainide cohorts (1.4 and 0.9, respectively). ([Table 15](#))

Proportions of patients in the *ILD Narrow Definition analysis dataset* with baseline GERD were somewhat lower than in the overall study population for the dronedarone, amiodarone and sotalol cohorts (27.3%, 28.1% and 28.6%, respectively) and slightly higher in the flecainide cohort (27.6%). Still, the proportions were similar across the four cohorts, both before and after matching.

Percentages of each cohort with COPD were fairly equal in the PS-matched data, and notably lower than in the pre-matched data for all but the flecainide cohort. Among the PS-matched dronedarone, amiodarone and sotalol cohorts, 12.9%, 17.2% and 15.6% of patients, respectively, had baseline COPD diagnoses. As with other morbidities, the proportion of the flecainide cohort with COPD was slightly higher in the PS-matched subset of patients (10.2%), than prior to PS matching.

Asthma appeared in fairly similar proportions of patients, by cohort, both before and after PS matching. Roughly one tenth of each PS-matched cohort had asthma diagnoses in their baseline records.

Proportions of patients with baseline bronchitis diagnoses were also consistent across cohorts in the *ILD Narrow Definition analysis dataset*, ranging from 7.6% of the dronedarone and flecainide cohorts to 9.7% of the sotalol cohort.

Prevalence of connective tissue disease was consistently low across the PS-matched cohorts, ranging from 3.6% of the dronedarone and sotalol cohorts to 4.2% of the flecainide cohort.

Exposure to toxins was rare among PS-matched patients, appearing in diagnoses of 0.3% or less of patients in each cohort.

#### 9.2.2.2.1.3 History of Medication Use

As in the overall *ILD Narrow Definition study population*, use of other anti-arrhythmics in the baseline was rare in the PS-matched cohorts. ([Table 14](#), [Table 15](#)) Only 76 patients in the entire *ILD Narrow Definition analysis dataset* had records indicating that they were dispensed other anti-arrhythmics. Those cases were fairly evenly distributed, representing between 0.4% and 0.5% of any one study drug cohort.

Proportions of patients dispensed agents associated with drug-induced pulmonary disease were also fairly balanced across cohorts of the analysis dataset. Roughly 90% of patients in each cohort had been dispensed at least one of these drugs. Those proportions in the PS-matched data were slightly lower than the corresponding proportions in the overall *ILD Narrow Definition study population* for the dronedarone and amiodarone cohorts, and slightly higher in the sotalol and flecainide cohorts.

About one third of patients in the *ILD Narrow Definition analysis dataset* had filled at least one prescription for a beta-blocker or anticoagulant (34.7% and 30.4%, respectively). Those were the most common potentially ILD inducing drugs found in the baseline records of patients in the ILD primary analysis. Completing the five most common drugs potentially associated with narrow definition ILD were ace inhibitors, hydrochlorothiazide, and nitrofurantoin, which were found respectively in the dispensing histories of 17.8%, 12.1% and 2.2% of patients.

As prior to PS matching, a total of two patients in the *ILD Narrow Definition analysis dataset* had records of receiving therapeutic oxygen treatment. Those appeared, one each, in the amiodarone and sotalol cohorts.

#### **9.2.2.2.2 Post-Index Date Characteristics**

##### **9.2.2.2.2.1 Patient Follow-Up Time**

Follow-up time for patients in the *ILD Narrow Definition analysis dataset* is summarized in **Table 16**. The average length of follow-up was similar for the four cohorts in the PS-matched data, falling between 985 days (32.8 months) and 1,054 days (35.1 months). The shortest and longest mean follow-up intervals were associated, respectively, with the dronedarone and sotalol cohorts.

**Table 16: ILD Narrow Definition Analysis Dataset Follow-up Time according to Study Drug Cohort: DoD Database - 20 July 2009 through 30 September 2014**

| Follow-up Time <sup>a</sup> | Dronedarone  |            | Amiodarone   |            | Sotalol      |            | Flecainide   |            |
|-----------------------------|--------------|------------|--------------|------------|--------------|------------|--------------|------------|

| Min                         | 8            |            | 3            |            | 8            |            | 12           |            |
| Max                         | 1,887        |            | 1,898        |            | 1,898        |            | 1,898        |            |

<sup>a</sup> Follow-up time is calculated as time from Index Date through the earliest of either end of eligibility, end of study or date of death.

#### 9.2.2.2.2 Index Treatment Episode

**Table 17** reports on lengths of index treatment episodes for patients' in the *ILD Narrow Definition analysis dataset*, according to study drug cohort. While more similar than prior to PS matching, lengths of index treatment episodes still varied across cohorts. The mean length of patients' index treatment episodes ranged from a low of 221 days (7.4 months) in the amiodarone cohort, to a high of 397 days (13.2 months) in the sotalol cohort. Index treatment episodes lasted less than one year for most patients, with median lengths ranging from 119 days in the amiodarone cohort (4 months) to 244 days in the sotalol cohort (8.1 months).

**Table 17: ILD Narrow Definition Analysis Dataset Length of Index Treatment Episode according to Study Drug Cohort: DoD Database - 20 July 2009 through 30 September 2014**

| Episode Length <sup>a</sup> | Dronedarone  |            | Amiodarone   |            | Sotalol      |            | Flecainide   |            |

<sup>a</sup> Length of index treatment episode is calculated as time from Index Date to the end of the index treatment episode.

### 9.2.3 ILD Narrow Definition Outcome Events

Pulmonary outcome events were identified via diagnosis codes comprising the narrow definition of ILD. Hospital records with admission dates after the patient Index Date through the end of the follow-up period were examined to identify suspected outcomes. A total of 113 cases of suspected Narrow Definition ILD were identified in the *ILD Narrow Definition analysis dataset*, and 52 of those were confirmed by the IAP-ILD. Nearly half the confirmed events (23 cases) occurred in the amiodarone cohort, with the remaining 29 cases appearing in relatively equal numbers in the dronedarone, sotalol and flecainide cohorts (9, 10 and 10 cases, respectively). ([Table 18](#))

[Table 18](#) also provides distributions of patients with confirmed cases of Narrow Definition ILD according to demographic and medical characteristics. Caution should be exercised in interpreting the numbers in this table, as the very small values in most cells (i.e.,  $n < 5$ ) preclude conducting a meaningful comparison of these patients' characteristics.

**Table 18: Adjudication Results of Suspected ILD Narrow Definition Outcome Events within the Follow-up Period according to Study Drug Cohort: DOD Database - 20 July 2009 to 30 September 2014**

Comparisons of incidence rates and hazard ratios for the ILD Narrow Definition primary analysis between each of the comparator cohorts versus the dronedarone cohort are found in **Table 19**. Total person-years of exposure for this analysis were calculated as the sum of person-years from Index Date through end of follow-up period for all patients in respective cohorts of the *ILD Narrow Definition analysis dataset*, with appropriate censoring applied to those cases with confirmed outcomes. Proportions of patients in each cohort remaining free of an ILD Narrow Definition outcome event for the same risk period are graphically displayed in a Kaplan-Meier graph (see **Figure 5**).

With more than double the number of confirmed events, the ILD Narrow Definition incidence rate in the amiodarone cohort was significantly higher than that of the dronedarone cohort (2.0 / 1,000 person-years of exposure versus 0.8 / 1,000 person-years of exposure,  $p=0.02$ ). The corresponding HR for this comparison was also significant (HR=2.5, 95% CI=1.1-5.3;  $p=0.02$ ). Incidence rates in the sotalol and flecainide cohorts were nearly identical to that of the dronedarone cohort (0.82 / 1,000 person-years of follow-up, 0.85/1,000 person-years of follow-up and 0.97 / 1,000 person-years of follow-up, respectively).

**Table 19: ILD Narrow Definition Analysis Dataset Incidence Rates (per 1,000 Person-Years of Follow-up) and Hazard Ratios of Confirmed Interstitial Lung Disease Events Identified during Follow-up Period: DOD Database - 20 July 2009 to 30 September 2014**

<sup>a</sup> The follow-up period (ILD Risk Period 1) begins the day after the Index Date and ends at the earliest occurrence of the ILD event, end of eligibility in the health plan, death or end of the study period.

<sup>b</sup> Person-years of follow-up is the sum of total days in ILD Risk Period 1 for all patients in the ILD Narrow Definition analysis dataset.

<sup>c</sup> Hazard ratio for dronedarone-flecainide comparison is a crude rate. Hazard ratio for dronedarone-amiodarone comparison is adjusted for study year of Index Date. Hazard ratio for dronedarone-sotalol comparison is adjusted for age on Index Date.

**Figure 5. ILD Narrow Definition Outcome Kaplan Meier Curve: Percent of Patients Remaining Event Free through End of Follow-up Period, ILD Narrow Definition Analysis Dataset**

### 9.3 OTHER ANALYSES

As only two SLD cases with the required laboratory data were identified in the SLD analysis dataset, the representativeness of those cases could not be assessed.

Three sensitivity analyses were conducted for the ILD outcome in order to address complexities of definition and outcome latency associated with ILD. Those separate analyses varied from the primary ILD analysis of this study by changing the definition of ILD used for baseline screening and outcome identification, and/or the risk period examined for ILD outcomes. Results of those sensitivity analyses are provided in [Appendix 13](#).

### 9.4 MANAGEMENT AND REPORTING OF ADVERSE EVENTS/ ADVERSE REACTIONS

This study was based on the secondary use of data; expedited reporting of AE/ADR is not required.

## 10. DISCUSSION

### 10.1 KEY RESULTS

This study took advantage of the availability in the electronic medical records of the US DoD Military Health System of very large populations of patients treated for atrial fibrillation to compare the rate of occurrence of two key suspected adverse events of concern: serious liver disease (SLD) and interstitial lung disease (ILD) associated with dronedarone (where possible signals of these events were noted). Dronedarone users were compared with users of amiodarone, dofetilide, sotalol, propafenone, and flecainide. Due to insufficient numbers of patients exposed to allow appropriate statistical analysis, the latter two drugs were not included in the outcome analyses.

In these granular longitudinal datasets, the selected cohorts allowed extensive identification of pre- and post-exposure events, as well as propensity score matching to assure the cohorts were comparable as to risk factors. The patients were active participants in the Military Health System between 20 July 2008 and 30 September 2014 and were required to be  $\geq$  age 18 and have a first-time prescription for their anti-arrhythmic therapy between 20 July 2009 and 31 March 2014 for inclusion in the study population. In addition, they were required to have at least 365 days of continuous enrollment prior to and including the date of their index prescription fill, during which time a diagnosis of atrial fibrillation had to appear. Additional screening for the specific outcome study populations (SLD and ILD) were applied to remove patients who might have experienced the outcome prior to their Index Date. The resulting possible cases of SLD and ILD were carefully and independently evaluated by specialty

(hepatic and pulmonary) clinical adjudicators to determine the likelihood of being valid outcome events.

### SLD Findings

With respect to SLD, the proportion of patients with possible cases prior to propensity score matching was highest in the amiodarone cohort (0.4%, 97/22,908) compared to the other three cohorts included in the outcome analysis (0.2%, 18/8,821; 0.2%, 12/6,740; and 0.2%, 9/5,015 for the dronedarone, sotalol and flecainide cohorts, respectively) (**Table 1**). **Table 8** shows the numbers of SLD cases in the PS-matched cohorts that were provided to the adjudicators for review. The proportions of suspected SLD in each PS-matched cohort were similar to the proportions prior to PS matching (0.2%, 7/4,123; 0.3%, 13/4,123; 0.1%, 5/4,123; and 0.2%, 7/4,123 for the dronedarone, amiodarone, sotalol and flecainide cohorts, respectively). None were adjudicated as confirmed SLD (though one was Indeterminate); thus, no comparison could be conducted. Therefore the data do not suggest an increased risk of SLD among dronedarone users.

Although several differences existed in the disease and medication profiles of the SLD analysis cohorts, it is notable that relatively high proportions of patients in all cohorts were diabetic and were obese. As the details of these conditions were not explored in the scope of this study, there is no clear way to evaluate their impact on any of the suspect cases.

Similarly, although a number of cases were exposed to medications that can be “hepatotoxic,” this study did not further examine the precise relationship of exposure to those types of drugs and occurrence of the outcome events adjudicated. It is important to point out that most of these compounds (e.g., acetaminophen) are seldom hepatotoxic except when there is exposure to high doses (as in the case of acetaminophen) or in the case of the very rare idiosyncratic reaction.

### ILD Narrow Definition Findings

**Table 1** shows some variation by cohort in proportions of the study populations with suspected cases of narrow definition ILD prior to propensity score matching. Among the cohorts ultimately included in the primary ILD outcome analysis, the highest proportion of cases with suspected outcomes were found in the amiodarone cohort (1.05%, 194/18,521). The corresponding proportions of the dronedarone, sotalol and flecainide study populations were respectively 0.8% (66/8,128), 0.7% (41/6,140) and 0.4% (20/4,195). Numbers of suspected cases of Narrow Definition ILD in the PS-matched cohorts are reported in **Table 18**. Proportions of each PS-matched cohort with suspected Narrow Definition ILD were similar to those found in the corresponding groups prior to matching (0.6%, 24/4,087; 1.03%, 42/4,087; 0.7%, 27/4,087; and 0.5%, 20/4,087%, respectively for the dronedarone, amiodarone, sotalol and flecainide cohorts). **Table 19** summarizes the PS-matched data analyzed to show incidence rates by cohort and Hazard Ratios comparing the risk of ILD through the end of the follow-up period for each comparator versus dronedarone. That table shows that patients in

this population taking amiodarone, compared to the dronedarone patients, had a 2.5 times higher risk of an ILD outcome event over the course of the follow-up period (95% CI:1.1-5.3), as defined by the narrow definition.

Three sensitivity analyses variously combining a broader definition of ILD and / or shorter risk period did not show significant differences from results of the primary analysis (See [Appendix 12](#)).

## **Other Risk Factors**

### **Age**

Among patients meeting initial screening criteria of the *ILD Narrow Definition study population*, the amiodarone cohort had the oldest patients on average (mean age=73.2 years) and the flecainide cohort the youngest (63.7 years).

### **Medical Conditions**

Some concomitant conditions are associated with signs and symptoms that are shared with some of the disorders found in these patients. For example, a history of GERD was the most common of the six potentially related diseases examined for the ILD group, appearing in baseline records of more than one fourth the patients in all study drug cohorts. Some authors have identified GERD as one potential risk factor, if not cause of ILD.<sup>18</sup> Further, baseline COPD was found in as few as 9% of patients (in the relatively young flecainide group), and as many as 24% of patients (in the relatively oldest cohort of amiodarone users). In contrast to GERD, COPD does not result in the same complex of signs and symptoms that mimic ILD, so this is likely not a confounder.

### **Drugs**

Nearly all patients had filled at least one prescription for a drug potentially associated with pulmonary disease; however, as in the case of SLD, most of the drugs sometimes associated with pulmonary fibrosis are only very rarely associated with the ILD outcome. The occasional oncological /anti-rheumatic pharmaceuticals that are more commonly associated with ILD were only seen in a few patients in these data.

In summary, the primary findings were that based upon our analysis of very large populations we did not find significant differences in the rate of SLD in PS- matched cohorts. In contrast, the amiodarone cohort had a significantly higher incidence and risk over time of a confirmed ILD diagnosis than the dronedarone cohort. The ILD incidence rates for sotalol and flecainide cohorts were essentially the same as dronedarone.

## 10.2 LIMITATIONS

### Strengths

This study has a number of strengths, including electronic medical record longitudinal data on large populations of patients treated for atrial fibrillation. This provided the investigators with a very large number of lives and level of detail covered in the system, and allowed them to initially conduct overall surveillance of the population to assure adequate power in the ultimate epidemiological study.

A notable advantage of conducting this study in the DoD data is reduction of some biases inherent in other healthcare databases, such as socioeconomic disparities which are minimized due to a common employer and a strong rank structure. That structure provides for:

- A group of patients who have at least one family member who is fully employed or retired with benefits. In addition to the comprehensive pharmacy and medical benefits, the negligible unemployment ensures that financial considerations are minimized as a barrier to patient compliance.
- A correlation of social and economic class with military rank rather than race or gender, facilitating examination of the impact of those demographic characteristics separate from socioeconomic considerations.

Further, the population is representative of the US population overall.<sup>17</sup>

The study was reviewed by a Steering committee with diverse clinical expertise, as well as adjudication panel experts with longstanding experience in their respective specialties who contributed their experience to defining and assessing outcomes. The adjudication review, despite absence of some laboratory and diagnostic data, reflected the experts' careful consideration of all of the cases as evidenced by varied and detailed discussions in the adjudication meetings.

### Weaknesses

There were also several limitations in this study.

Although the DoD database afforded the investigators large amounts of data, these data nonetheless have limitations that affect the interpretation of results. Those included:

- Limited laboratory results data, which might have allowed for more precise adjudication of cases:
  - For SLD cases, the hepatologists found the absence of specific laboratory data rather limiting
  - For ILD cases, the lack of results of pulmonary function tests as well as lung scan results likewise were limiting
- Limited data on / difficult to ascertain smoking status

- Possible underreporting of some conditions (e.g., obesity, alcoholism, smoking) which may be relevant to outcomes
- Insufficient patients to include dofetilide and propafenone in the outcome analyses
- The fact that patients were primarily white, by race.

In addition, although SLD events have been reported to occur in association with the anti-arrhythmic drugs included in this study, since no cases were detected it is possible the cohorts were not large enough to detect actual cases of SLD, or that other features of cohort selection may have been factors in this finding. This may be a result of differences between this study and the earlier internal Sanofi study used as background to estimate the study's required sample size. The current study likely used more broadly inclusive definitions of SLD and ILD, while restricting outcomes to those that occurred in hospital or skilled nursing facilities. The longer baseline period (365 days in this study versus six months in the previous study) also meant that more patients with pre-existing conditions were screened out of the current analyses.

Finally, upon reviewing the individual cases there were often one or more concomitant conditions that were associated with SLD or ILD, respectively. For example, several SLD profiles included patients with recurrent congestive right heart failure that might have manifest as chronic passive hepatic congestion; similarly, a number of pulmonary cases also had sarcoidosis or multiple pulmonary conditions, and in many cases there were no pulmonary scans to allow clearer differentiation.

### **10.3 INTERPRETATION**

This study was undertaken in response to signals of SLD and ILD potentially associated with dronedarone.

With regard to SLD, this study provides no support for the signal. The finding of no confirmed cases of SLD suggests no increased risk of SLD with use of dronedarone versus the comparator anti-arrhythmics.

The study did find confirmed cases of ILD in all study drug cohorts. Incidence rate comparisons and survival analyses showed significantly higher rates of ILD, as well as risk through the follow-up period, among amiodarone than dronedarone users. These results, therefore, provide no evidence of increased risk of ILD associated with dronedarone use.

### **10.4 GENERALIZABILITY**

The DoD data have been shown to be representative of the broader US population.<sup>17</sup> As such, results of the study should be generalizable to US patients with similar demographic and medical characteristics.

## 11. OTHER INFORMATION

All information has been included in relevant report sections. There is no other information to report.

## 12. CONCLUSION

Results from this retrospective cohort study in a large EMR database show that the incidence of SLD and ILD in patients with AF treated with dronedarone are not different than in patients using most comparator drugs. Few SLD cases were identified, and none were adjudicated as confirmed SLD. Less than 1 case of ILD per 1,000 person-years was estimated in dronedarone users. Amiodarone was associated with an adjusted 2.5-fold higher risk of ILD than dronedarone with a point estimate of 2 cases per 1,000 person-years.

| <b>APPENDIX 12: PROPENSITY SCORE GENERATION AND MATCHING .....</b>                                                                                             | <b>1</b>  |
| A. INTRODUCTION.....                                                                                                                                           | 2         |
| B. PROPENSITY SCORE GENERATION.....                                                                                                                            | 3         |
| C. GENERATE PROPENSITY SCORES FROM REDUCED LOGISTIC REGRESSION MODEL.....                                                                                      | 9         |
| D. PROPENSITY SCORE MATCHING .....                                                                                                                             | 9         |
| E. VALIDATE PROPENSITY SCORE BALANCE ON BASELINE VARIABLES.....                                                                                                | 11        |
| F. VALIDATE PROPENSITY SCORE BALANCE ON ILD NARROW DEFINITION OUTCOME.....                                                                                     | 26        |
| G. TEST CONSTANCY OF HAZARD RATIO ACROSS PS-QUINTILES FOR EACH COHORT .....                                                                                    | 27        |

|                                                                                                                    |          |
|--------------------------------------------------------------------------------------------------------------------|----------|
| <b>APPENDIX 13: ILD SENSITIVITY ANALYSES .....</b>                                                                 | <b>1</b> |
| A. ILD SENSITIVITY ANALYSES .....                                                                                  | 2        |
| B. DEFINITIONS OF ILD FOR EXCLUSIONARY SCREENING AND<br>OUTCOME EVENT IDENTIFICATION IN SENSITIVITY ANALYSES ..... | 2        |
| C. ILD BROAD DEFINITION DATASETS.....                                                                              | 7        |
| D. SENSITIVITY ANALYSES RESULTS.....                                                                               | 20       |
| SENSITIVITY ANALYSES PARAMETERS .....                                                                              | 20       |
| ILD SENSITIVITY ANALYSIS 1 .....                                                                                   | 22       |
| ILD SENSITIVITY ANALYSIS 2 .....                                                                                   | 23       |
| ILD SENSITIVITY ANALYSIS 3 .....                                                                                   | 26       |
| <b>APPENDIX 14. DRONEDARONE EPIDEMIOLOGY STUDY PROTOCOL .....</b>                                                  | <b>1</b> |
| <b>APPENDIX 15. STATISTICAL ANALYSIS PLAN – DOD .....</b>                                                          | <b>1</b> |

**APPENDIX 1. SURVEILLANCE OF DRONEDARONE USE AND  
OCCURRENCES OF SERIOUS LIVER  
INJURY/DISEASE AND INTERSTITIAL LUNG  
DISEASE OUTCOME EVENTS – STUDY REPORT**

# A SURVEILLANCE REPORT ON DRONEDARONE USE AND OCCURRENCES OF SERIOUS LIVER INJURY AND INTERSTITIAL LUNG DISEASE

STUDY REPORT

FOR  
SANOFI

Prepared by  
The Degge Group, Ltd.

2 March 2017

---

## A Surveillance Report on Dronedarone Use and Occurrences of Serious Liver Injury/Disease and Interstitial Lung Disease

---

### ADMINISTRATIVE DETAILS

**Client**                      **Sanofi Pharmaceuticals, Inc.**

Contacts                      Juhaeri Juhaeri, PhD, FISPE                      juhaeri.juhaeri@sanofi-aventis.com  
                                         *VP and Head Global Safety Sciences*                      (908) 981-3718

                                         Chuntao Wu, MD, PhD                      chuntao.wu@sanofi.com  
                                         *Senior Director, Epidemiology*                      (908) 981-4554

Address                      55 Corporate Drive.  
                                         Bridgewater, NJ 08807

**Vendor**                      **The Degge Group, Ltd.**

Contacts                      Judith K Jones, MD, PhD, FISPE                      jkjones@deggegroupp.com  
                                         *President & CEO*

                                         Earl Goehring                      egoehring@deggegroupp.com  
                                         *Managing Director, Research*

                                         Arlene Tave, MA                      atave@deggegroupp.com  
                                         *Assistant Managing Director, Research*

                                         Ruby Vendiola                      rvendiola@deggegroupp.com  
                                         *Senior Analyst / Quality Assurance Manager*

                                         Rhonda L Bohn, MPH, ScD, FISPE                      rlbohn@comcast.net  
                                         *Consultant Epidemiologist*

Address                      9302 Lee Highway, Suite 700  
                                         Fairfax, VA 22031

Telephone                      (571) 490-8020                      Fax (571) 490-8408

# **A Surveillance Report on Dronedarone Use and Occurrences of Serious Liver Injury/Disease and Interstitial Lung Disease**

For  
Sanofi

Prepared by  
The Degge Group, Ltd.

2 March 2017

---

## **1. BACKGROUND**

---

Dronedarone (Multaq®) is an anti-arrhythmic drug with effects from all four classes of the Vaughan Williams classification indicated for treatment of patients with non-permanent atrial fibrillation (AF).<sup>1</sup> The recommended dose is 400 mg twice daily in adults. Dronedarone was authorized on 1 July 2009 in the United States. It is currently marketed in 32 countries in the Americas, Europe, and Asia.

Post-marketing analysis of spontaneous reports associated with dronedarone use identified safety signals related to serious liver injury/disease (SLD), and interstitial lung disease (ILD), which were also seen in association with the other treatments, notably amiodarone.<sup>2</sup> Two case reports that resulted in transplantation prompted the initiation of epidemiologic studies to examine dronedarone use and the occurrence of serious liver related injury.

As the first step toward an epidemiologic analysis, Sanofi contracted with The Degge Group Ltd. (Degge) to develop a comprehensive strategy for surveillance of a large proportion of the US population exposed to dronedarone. The goal of the surveillance was, to determine the feasibility of detecting, characterizing, and quantifying the occurrence of serious liver injury and interstitial lung disease associated with its use of dronedarone and other anti-arrhythmic drugs. Degge proposed a multi-dimensional program that utilized external data sources to meet these objectives.

---

## 2. OBJECTIVES

---

The primary and secondary objectives of the dronedarone surveillance study were:

- a. To count numbers of new users of dronedarone and comparator anti-arrhythmic drugs identified from administrative claims databases and electronic health records (EHR) on a quarterly basis. This systematic monitoring of databases representative of the general population would inform the timing at which a sufficiently powered formal epidemiologic study could be conducted.
- b. To identify the number of SLD and ILD occurrences among new users of dronedarone and comparator anti-arrhythmic drugs. Identification and profiling of SLD and ILD occurrences would inform the case definition of these events used in the formal epidemiologic study, and provide insight into the demographic and clinical profiles of patients associated with these cases.

---

### 3. DATA SOURCES

---

One electronic health record (EHR) system (US Department of Defense Military Health System Database), and one administrative claims database (HealthCore/HIRD) were identified as sources to monitor the use of dronedarone in the general population. Those two databases had the largest number of dronedarone users among three databases identified as potential sources. The database identified, but not selected for the surveillance activity, was I3/Ingenix Normative Health Information (NHI) Database.

#### 3.1 HEALTH RESEARCHTX / US DEPARTMENT OF DEFENSE (DOD)

Health ResearchTx (HRTX) is a health research organization that has a unique partnership with the United States Department of Defense (DoD) to leverage their Military Health System (MHS) Database to improve health outcomes, lower costs, and increase force readiness. The MHS provides health care for both active duty and retired military members and their families (beneficiaries).

As a single payer system, MHS provides uniform medical coverage and pharmacy benefits for more than 100 million covered lives. The database stores over 30 billion archived records, 5 billion online health records spanning more than 17 years, 260 years of ePrescribing and comparable decades of prescription, and includes both inpatient and outpatient data. Active duty members comprise approximately 17% of the MHS covered population. Records of veterans who receive medical coverage through the Veterans Administration are not captured in the DoD database.

The MHS provides two types of care to its beneficiaries. Direct care is provided through a network of military hospitals and clinics and while purchased care is delivered by civilian providers financed through managed care contracts and fee-for-service reimbursements. Direct care accounts for 37% of all care provided. All administrative events generated by either a direct care or purchased care encounter are tracked in the central MHS Data Repository (MDR). Examples of data recorded in the MDR include patient demographic data, provider information (provider ID, specialty, and facility), diagnostic codes (ICD-9-CM codes for outpatient visits; Diagnosis-Related Group (DRG) codes for inpatient stays) and Current Procedural Terminology (CPT®) codes for procedures. Extensive patient information including address, age, race, rank, and active duty status is also stored within the MDR via connections with the Defense Eligibility Enrollment Reporting System (DEERS). The DoD database also includes records from the military's electronic medication ordering system called the Pharmacy Data Transaction System (PDTS). PDTS includes electronically coded dispensing details of both direct care and purchased care outpatient medication orders, including the prescribed drug name and National Drug Code (NDC), dose, quantity, refills and prescribing provider.

### **3.2 HEALTHCORE / HIRD**

The HealthCore Integrated Research Database™ (HIRD) was monitored for new dronedarone users beginning on the product launch date. The HIRD represents a diverse spectrum of longitudinal claims data and the largest commercially-insured population in the United States (Southeastern, Mid-Atlantic, Northeastern, Central, and Western regions). It contains eligibility, medical, and pharmacy claims for more than 30 million fully-insured members. In addition, laboratory data are available for a subset of approximately 13+ million patients. Outpatient and inpatient clinical data contained in the HIRD are coded with International Classification of Disease (ICD) diagnosis and procedure codes, Code of Procedural Terminology (CPT) codes, and the Healthcare Common Procedure Coding System (HCPCS). Outpatient dispensing records are coded with National Drug Codes (NDCs) as well as by Generic Product Indicators (GPI), which include the drug name, dosage form and drug strength.

---

## 4. METHODS

---

### 4.1 Epidemiology Steering Committee

An Epidemiology Steering Committee (ESC) was convened to oversee the scientific integrity, validity of the study protocol, to assess of study quality and conduct, as well as, the scientific quality of interim reports and the final study report.

The ESC consisted of seven individuals. In addition, to the Committee Chair and Co-Chair, there were five individuals who were experts in one or more of the following areas: hepatology, cardiology, liver-associated injury, epidemiology, biostatistics, and regulatory drug safety.

#### Epidemiology Steering Committee Members

- Judith K Jones, MD, PhD, FISPE, **Chair**, *The Degge Group, Ltd., Fairfax, Virginia*
- Rhonda L Bohn, ScD, MPH, FISPE, **Co-Chair**, *Rhonda L Bohn, LLC, Boston, Massachusetts*
- Toby Barbey, MD, *Cardiologist, Social & Scientific Systems, Silver Spring, Maryland*
- Michael Gaziano, MD, MPH, *Cardiologist/Epidemiologist, Brigham & Women's Hospital, Boston, Massachusetts* [NOTE: Resigned 25 August 2014. A replacement was not identified.]
- James H. Lewis, MD, *Hepatologist, Georgetown University, Washington, District of Columbia*
- Captain Sally Tamayo, MD, *Cardiologist, Navy Medical Center, US Department of Defense, Portsmouth, Virginia*
- Susan T. Sacks, PhD, FISPE, *Epidemiologist/Statistician, Independent, Scottsdale, Arizona*

### 4.2 Study Design

A cohort design was employed to conduct the surveillance monitoring.

### 4.3 Study Period

The surveillance study period started on 20 July 2008. This provided a one-year screening period prior to the surveillance monitoring start date of 20 July 2009, the launch date for dronedarone. Monitoring continued through 31 March 2014 by which time sufficient numbers of dronedarone users were identified in the DoD and HIRD databases for the initiation of the pharmacoepidemiology study.

### 4.4 Study Populations

Study populations in the two databases included patients treated for newly occurring atrial fibrillation (AF) with either dronedarone or one of the specified comparator anti-arrhythmic drugs: amiodarone, sotalol, flecainide, dofetilide, or propafenone.<sup>3</sup> The comparator drugs were chosen as they are also used in the treatment of AF.

#### 4.4.1 Dronedarone Population

The two data sources concurrently identified patients who were new users of dronedarone via National Drug Codes (NDC (claims data)) or drug names (EHR system) starting from the date of product launch 20 July 2009. See [Appendix 1](#) for study population definitions. New users of dronedarone were required to have an AF diagnosis in the 12 months prior to the date of their first study drug fill (Index Date) and no use of dronedarone in the same 12-month period (baseline period). Baseline use of study drugs other than dronedarone (i.e., one of the comparator drugs) during the baseline period were permitted. See [Figure 1](#).

**Figure 1. Study Population Selection**

#### 4.4.2 Drug Comparator Populations

New users of amiodarone, sotalol, flecainide, dofetilide, and propafenone were identified in each data source using the same criteria applied to the dronedarone population.

That is, new users, of each comparator drug were defined as having an AF diagnosis in their baseline period, and no claims (or dispensing record) for the same drug in the 12 months prior to the Index Date. Baseline fills of dronedarone or one of the other comparator study drugs during the baseline period were permitted.

Patients were removed from the study populations for the following occurrences:

- Less than 365 days of eligibility in the baseline period;

- No AF in the baseline period;
- Index study drug in the baseline period; and
- Date of death preceding their Index Date.

The following exclusionary screening was added during the 2013-Q2 reporting period. These were specific to the Epidemiology Study Protocol inclusion / exclusion criteria.

- Less than 18 years old on the Index Date;
- Cancer or organ transplant in the baseline period;
- HIV in the baseline period;
- Pregnancy codes 280 days prior/post index date.

---

## 5. COHORT MONITORING

---

For the surveillance, existing new users of dronedarone and comparator drugs (amiodarone, sotalol, flecainide, dofetilide, and propafenone) were identified in records dated between 20 July 2009 and 31 December 2011 (retrospective data count). National Drug Codes (NDCs) were used to identify study drugs in the HIRD database, and dispensing data / NDC codes identified the study drugs in the DoD database.

Beginning 1 January 2012, new users of the study drugs of interest were identified prospectively in each data source (DoD, HIRD) at quarterly intervals. During the prospective monitoring period only new unique patients starting a study drug of interest in each quarter were added to the cumulative count. Evidence of a diagnosis of AF in the 12-month baseline was required in all cases.

Cumulative numbers of new users of each study drug were tabulated as study drug cohorts in each database. Patients were followed as members of their index study drug cohort until any of the following occurred:

- Discontinued a study drug of interest;
- Switched to another study drug of interest;
- Were no longer eligible members in the health plans under study;
- Occurrence of a serious liver injury/disease outcome occurrence / interstitial lung disease outcome occurrence; or
- Patient died.

For all of the instances above (except for loss of eligibility and death), new study drug users were followed until the end of the study monitoring period.

Study drug discontinuation was defined as having no subsequent dispensing records for the index medication starting from the index prescription dispensed date plus the days supply value plus 60 days to account for potential non-adherence and/or delays in medication refill patterns.

Switching was defined as a claim or dispensing record for another study drug either during or following the duration of continuous therapy with the index drug, regardless of whether or not there was another claim for the index study drug on a later date. The time at which a patient switched or added another study drug (augmentation) terminated that patient's time in that index drug cohort. As stated earlier, although participation in the study cohort was terminated, patients were followed, until the end of the study monitoring period.

The schematic below (**Figure 2**) illustrates cohort follow-up.

**Figure 2. Cohort follow-up diagram**

As illustrated above, two users of dronedarone would be identified in the initial retrospective count (Patient B, Patient C); Patient A and Patient G would be identified prospectively. Similarly, one study drug comparator patient (Patient E) would be identified during the initial patient counts and two additional comparator drug users (Patient C & D) would be identified during prospective surveillance. One study drug user (Patient F) would not be counted in the initial retrospective or prospective count since use started in the six months prior to the 20 July 2009 start date. Patient C would be counted twice; once for dronedarone and once for a comparator drug, since the comparator study drug start date is greater than 60 days after their last dronedarone claim date plus days supply value and there is no use of either drug in the 12 months prior to study drug use.

---

## 6. OUTCOMES OF INTEREST – SURVEILLANCE DEFINITIONS

---

There were two surveillance outcome events of interest:

- Serious liver injury/disease (SLD)
- Interstitial lung disease (ILD)

### 6.1 Serious Liver Injury/Disease (SLD) Surveillance Outcome Definition

The number of SLD outcome event occurrences was identified by individual diagnosis code or procedure code that met the study SLD definition specified in the protocol. Text descriptions, including diagnoses and procedures and database specific codes, as well as lab values, were used to identify occurrences of SLD in the two databases. The initial SLD definition was based on the OMOP Acute Liver Failure definition.<sup>4</sup> **Table 1** lists the initial SLD definition used for the surveillance program, which was designed to be maximally sensitive.

**Table 1. Initial SLD Surveillance Definition**

| ICD-9-CM Diagnosis  |                                                                |
|---------------------|----------------------------------------------------------------|
| 570                 | Acute and subacute necrosis of liver                           |
| 571.5               | Cirrhosis of liver without mention of alcohol                  |
| 572.2               | Hepatic coma                                                   |
| 572.4               | Hepatorenal syndrome                                           |
| 573.0               | Chronic passive congestion of liver                            |
| 573.3               | Hepatitis, unspecified                                         |
| 573.8               | Other specified disorders of liver                             |
| 573.9               | Unspecified disorder of liver                                  |
| 782.4               | Jaundice, unspecified                                          |
| 789.1               | Hepatomegaly                                                   |
| 790.4               | Nonspecific elevation of levels of transaminase or LDH         |
| 790.5               | Other or nonspecified abnormal serum levels                    |
| 791.4               | Biliuria                                                       |
| 794.8               | Nonspecific abnormal results of liver function test            |
| ICD-9-CM Procedures |                                                                |
| 50.11               | Closed (percutaneous) [needle] biopsy of liver                 |
| 50.12               | Open biopsy of liver                                           |
| 50.13               | Transjugular liver biopsy                                      |
| 50.14               | Laparoscopic liver biopsy                                      |
| 50.5                | Liver transplant                                               |
| 50.51               | Auxiliary liver transplant                                     |
| 50.59               | Other transplant of liver                                      |
| 50.91               | Percutaneous aspiration of liver                               |
| CPT Procedure Codes |                                                                |
| 47000               | Biopsy of liver, needle; percutaneous                          |
| 47001               | Biopsy of liver, needle; done at time of other major procedure |
| 47100               | Biopsy of liver, wedge                                         |
| 47135               | Liver allotransplantation; orthotopic, partial or whole,       |
| 47136               | Liver allotransplantation; heterotopic, partial or whole,      |
| 78205               | Liver imaging (SPECT);                                         |
| 78206               | Liver imaging (SPECT); with vascular flow                      |

Revisions to the SLD surveillance definition during the course of the surveillance program included:

The following diagnosis codes were added:

- 277.4 Disorder of bilirubin excretions
- 572.8 Other sequelae of chronic liver disease (added 23 October 2013)
- V42.7 Liver replaced by transplant (added 12 March 2013)

The following diagnosis codes were removed:

- 573.4 Hepatic infarction
- 789.1 Hepatomegaly
- 790.4 Nonspecific elevation of levels of transaminase or LDH
- 790.5 Other or nonspecified abnormal serum levels
- 791.4 Biliuria

The ESC approved all revisions. See [Appendix 2](#) for the final expanded SLD surveillance definition used for the Quarterly Reports.

During the initial retrospective period, as well as, each quarterly monitoring period, the number of SLD occurrences was tabulated. Only the first occurrence of an SLD diagnosis code that occurred after the patient's Index Date was counted, regardless of the number of different liver injury diagnosis codes recorded after follow-up.

The time period for identification of serious liver injury occurrence began the day after the Index Date and continued to the end of the monitoring period unless censored, and patients were continuously followed for up to five years or end of the study period.

## 6.2 Interstitial Lung Disease (ILD) Surveillance Outcome Definition

The number of ILD outcome event occurrences was identified by individual diagnosis codes that met the study ILD definition in the protocol. Text descriptions, including diagnoses and database specific codes, were used to identify occurrences of ILD in the two databases.

The number of ILD outcome event occurrences was identified by individual diagnosis codes that met the study ILD definition in the protocol. The initial ILD definition was provided by Wanju Dai, MD, PhD, mirrored the diagnosis codes described in a systemic review for the FDA's Mini-Sentinel Project by Natalie Jones et al.<sup>5</sup> **Table 2** lists the initial ILD definition used for the surveillance program, which was designed to be maximally sensitive.

The ILD surveillance definition was revised during the course of the surveillance program.

**Table 2. Initial ILD Surveillance Definition**

| Code Type | DESCRIPTION                                                  |
|-----------|--------------------------------------------------------------|
| 495.9     | Unspecified allergic alveolitis and pneumonitis              |
| 515       | Postinflammatory pulmonary fibrosis                          |
| 516.3     | Idiopathic fibrosing alveolitis                              |
| 516.8     | Other specified alveolar and parietoalveolar pneumonopathies |
| 516.9     | Unspecified alveolar and parietoalveolar pneumonopathy       |

The following diagnosis codes were added:

- 516.30 Idiopathic interstitial pneumonia, not otherwise specified (IIP) – added 12 Mar 2013
- 516.31 Idiopathic pulmonary fibrosis (IPF) – added 12 Mar 2013
- 516.32 Idiopathic non-specific interstitial pneumonitis (NSIP) – added 12 Mar 2013
- 516.33 Acute interstitial pneumonitis (AIP) – added 12 Mar 2013
- 516.34 Respiratory bronchiolitis interstitial lung disease (RB-ILD) – added 12 Mar 2013
- 516.35 Idiopathic lymphoid interstitial pneumonia (LIP) – added 12 Mar 2013
- 516.36 Cryptogenic organizing pneumonia (COP) – added 12 Mar 2013
- 516.37 Desquamative interstitial pneumonia (DIP) – added 12 Mar 2013

The ESC approved all revisions. See [Appendix 3](#) for the final expanded ILD surveillance definition for the Quarterly Reports.

During the initial retrospective period, as well as, each quarterly monitoring period, the number of ILD occurrences was tabulated. Only the first occurrence of an ILD diagnosis code that occurred after the patient's Index Date was counted, regardless of the number of different ILD diagnosis codes after the start of follow-up.

### 6.3 Patient Profiling

Profiles were generated from patient records for approximately 50 SLD patients and 50 ILD patients from each database. Degge provided a template to HealthCore, illustrating the overall format layout, and identifying the data elements to be included in the profiles they generated. The Patient Profiles helped to inform the outcome event definitions to use in the targeted epidemiologic study, and provided insight into the demographic, clinical profile, and drug switching patterns in the surveillance study populations.

---

## 7. STATISTICAL ANALYSIS

---

### 7.1 Analytic Approach

The basis for the analysis of the monitoring component of this study was counts. The number of new users of dronedarone, amiodarone, sotalol, flecainide, dofetilide, and propafenone, and the number of new occurrences of SLD and ILD were tabulated during the initial retrospective portion, and for each quarterly interval in the prospective data collection. Individual database reports for the retrospective period report and the prospective quarterly reports for DoD and HIRD are provided in [Appendix 4](#) and [Appendix 5](#), respectively.

### 7.2 Building of Case Algorithms

Patient profiles generated for cases with a suspected SLD or a suspected ILD outcome event were each reviewed to help more clearly define study definition criteria for SLD and ILD outcome events. Included in the patient profiles were demographic and clinical variables, including diagnosis and procedure codes during outpatient visits and inpatient stays, outpatient drug use and, if available, laboratory and other clinical reports. They provided insight into co-morbid conditions and other factors that may be associated with the two outcome events of interest. Patient profile examples for SLD and ILD are provided in [Appendix 6](#).

### 7.3 Sample Size

Sample-size requirements for the analyses were estimated based on the following statistical design parameters and assumptions. They are based on the population size prior to propensity score matching.

- **Type of Analysis:** Comparison of event-free “survival” time between the dronedarone-exposed cohort and each comparator (reference) cohort, by means of the log-rank test, or Cox proportional-hazards regression
- **Alpha Level:** 0.05 ( $p \leq 0.05$  considered statistically significant)
- **Power:** 80% (80% chance of obtaining a significant result if a true difference in event-free survival between cohorts exists, and is of an important magnitude)
- **Effect Size of Importance:** Hazard Ratio = 3.0
- **Incidence Rate in the Comparator (Reference) Group:** 1 event/1,000 patient-years
- **Group size Ratio:** 1:1 (equal numbers of dronedarone and comparator subjects), consistent with 1:1 propensity-score matching
- **Accrual Interval:** 5 years (July 2009 through March 2014)
- **Follow-up Beyond Last Accrual:** 6 months (Index Dates ranged from July 2009 through March 2014)

**Table 3** shows the number of dronedarone subjects required to provide 80% power, at the 0.05 alpha level, to detect hazard ratios of 2.0, 3.0, and 4.0, for various values of the comparator (reference) group incidence rate:

**Table 3. Sample Size Calculation**

| Incidence Rate (Events / patient-years In the Comparator Group) | # of Subjects Needed in Each Cohort |              |        |
|-----------------------------------------------------------------|-------------------------------------|--------------|--------|
|                                                                 | HR=2.0                              | HR=3.0       | HR=4.0 |
| 0.01%/year (1 / 10,000 patient-years)                           | 108,947                             | 38,553       | 22,698 |
| 0.02%/year (1 / 5,000 patient-years)                            | 54,477                              | 19,278       | 11,351 |
| 0.05%/year (1 / 2,000 patient-years)                            | 21,800                              | 7,714        | 4,542  |
| 0.1%/year (1 / 1,000 patient-years)                             | 10,906                              | <b>3,860</b> | 2,273  |
| 0.2%/year (1 / 500 patient-years)                               | 5,460                               | 1,933        | 1,138  |
| 0.5%/year (1 / 200 patient-years)                               | 2,192                               | 776          | 457    |
| 1%/year (1 / 100 patient-years)                                 | 1,103                               | 391          | 231    |

[Software used to produce calculations: PS - Power and Sample Size Calculations, version 3.0, by W. D. Dupont and W. D. Plummer (Vanderbilt University).]

The incidence rate of 1 per 1,000 patient years was considered a sufficiently conservative estimate to use in the sample size calculations. Therefore, for a HR of 3.0, the minimum required sample size was 3,860 patients per study drug cohort.

The *dofetilide* and *propafenone* cohorts did not meet the required sample size of 3,860 patients. They were excluded prior to the propensity score matched process.

Background data to support the sample size and power calculations were provided by Sanofi from a retrospective cohort study conducted internally by Sanofi in 2011. That study used integrated medical and prescription claims data from the LabRx database (Safety Study Report – Dronedarone, SR33589, GPE Pharmacoepidemiology, August 2, 2011). That study found the following:

| Outcome Studied                              | Incidence Rate / 1,000 PYs |
|----------------------------------------------|----------------------------|
| Incidence of acute liver injury <sup>‡</sup> | 7.6 (0.9 - 14.2)           |
| Incidence of interstitial lung disease       | 21.9 (10.5 - 33.4)         |

<sup>‡</sup> Defined as a primary diagnosis of acute or sub-acute necrosis of liver, hepatic coma, toxic hepatitis, or liver transplant in hospital by ICD-9-CM and CPT codes.

It was determined at the ESC meeting on 30 September 2014 that the sample size requirement of 3,860 had been met in four of the six drug cohorts in both databases. There were sufficient patient numbers to initiate the Dronedarone Epidemiology Study.

Final patient numbers indicating sufficient sample size in the dronedarone, amiodarone, sotalol, flecainide study drug cohorts to move forward with the Epidemiology Study Protocol in both the DoD Database and HIRD Database are provided in **Table 4** and **Table 5**, respectively.

**Table 4. Final DoD Patient Counts Indicating Sufficient Sample Size to Begin Epidemiology Study; US DoD Database: 20 July 2009 to 31 March 2014**

| Baseline Exclusionary Screening Description                       | Dronedarone  |             | Amiodarone    |             | Sotalol      |             | Flecainide   |             | Dofetilide |             | Propafenone  |             |

| 1. Among the HealthCore Integrated Research Database <sup>SM</sup> (HIRD) population including both fully insured and administrative services only (ASO) members, for whom claims profiles can now be shared externally outside of HealthCore, Inc. <sup>4</sup> The Epidemiology Study will be conducted using this patient population. Only the index study drug will be counted, therefore a patient is only counted once. |                           |             |                          |             |                       |             |                          |             |                          |             |                           |             |
| 2. Additional screening to reflect Epidemiology Study Protocol.                                                                                                                                                                                                                                                                                                                                                               |                           |             |                          |             |                       |             |                          |             |                          |             |                           |             |

---

## **8. LIMITATIONS**

---

This is primarily a monitoring effort as a preface to planning a formal epidemiologic study. The number of patients dispensed dronedarone or comparator medications, and the number of patients identified with an occurrence of SLD or ILD are not exact numbers; they were estimates for planning the epidemiologic study.

Administrative claims data lack specificity in some diagnostic codes. Patient profiles helped to more clearly define study definition criteria for SLD and ILD outcome events.

---

## **9. QUALITY ASSURANCE**

---

The study was conducted in accordance with Guidelines for Good Pharmacoepidemiology Practice established by the International Society of Pharmacoepidemiology and Therapeutic Risk Management.<sup>6</sup> The Degge Group, Ltd, its employees, and consultants followed and documented adherence to these guidelines.

## Atrial Fibrillation

| <b>ICD-9 CODE</b> | <b>Description</b>  |
|-------------------|---------------------|
| 427.31            | Atrial fibrillation |

## APPENDIX 2. SERIOUS LIVER INJURY/DISEASE DEFINITION

### Serious Liver Injury/Disease Codes:

| Code Type                  | DESCRIPTION                                                    |
|----------------------------|----------------------------------------------------------------|
| <b>ICD-9-CM Diagnoses</b>  |                                                                |
| 277.4*                     | Disorders of bilirubin excretion                               |
| 570                        | Acute and subacute necrosis of liver                           |
| 571.5                      | Cirrhosis of liver without mention of alcohol                  |
| 572.2                      | Hepatic coma                                                   |
| 572.4                      | Hepatorenal syndrome                                           |
| 572.8*                     | Other sequelae of chronic liver failure                        |
| 573.0                      | Chronic passive congestion of liver                            |
| 573.3                      | Hepatitis, unspecified                                         |
| 573.8                      | Other specified disorders of liver                             |
| 573.9                      | Unspecified disorder of liver                                  |
| 782.4                      | Jaundice, unspecified                                          |
| 794.8                      | Nonspecific abnormal results of liver function test            |
| V42.7*                     | Liver replaced by transplant                                   |
| <b>ICD-9-CM Procedures</b> |                                                                |
| 50.11                      | Closed (percutaneous) [needle] biopsy of liver                 |
| 50.12                      | Open biopsy of liver                                           |
| 50.13                      | Transjugular liver biopsy                                      |
| 50.14                      | Laparoscopic liver biopsy                                      |
| 50.5                       | Liver transplant                                               |
| 50.51                      | Auxiliary liver transplant                                     |
| 50.59                      | Other transplant of liver                                      |
| 50.91                      | Percutaneous aspiration of liver                               |
| <b>CPT Procedures</b>      |                                                                |
| 47000                      | Biopsy of liver, needle; percutaneous                          |
| 47001                      | Biopsy of liver, needle; done at time of other major procedure |
| 47100                      | Biopsy of liver, wedge                                         |
| 47135                      | Liver allotransplantation; orthotopic, partial or whole,       |
| 47136                      | Liver allotransplantation; heterotopic, partial or whole,      |
| 78205                      | Liver imaging (SPECT);                                         |
| 78206                      | Liver imaging (SPECT); with vascular flow                      |

The following codes were removed from the original definition:

- 573.4 Hepatic infarction
- 789.1 Hepatomegaly
- 790.4 Nonspecific elevation of levels of transaminase or LDH
- 790.5 Other or nonspecified abnormal serum levels
- 791.4 Biliuria

---

## APPENDIX 3. INTERSTITIAL LUNG DISEASE DEFINITION

---

### Interstitial Lung Disease (ILD)

| Code Type                 | DESCRIPTION                                                      |
|---------------------------|------------------------------------------------------------------|
| <b>ICD-9-CM Diagnoses</b> |                                                                  |
| 495.9                     | Unspecified allergic alveolitis and pneumonitis                  |
| 515                       | Postinflammatory pulmonary fibrosis                              |
| 516.3                     | Idiopathic fibrosing alveolitis                                  |
| 516.30*                   | Idiopathic interstitial pneumonia, not otherwise specified (IIP) |
| 516.31*                   | Idiopathic pulmonary fibrosis (IPF)                              |
| 516.32*                   | Idiopathic non-specific interstitial pneumonitis (NSIP)          |
| 516.33*                   | Acute interstitial pneumonitis (AIP)                             |
| 516.34*                   | Respiratory bronchiolitis interstitial lung disease (RB-ILD)     |
| 516.35*                   | Idiopathic lymphoid interstitial pneumonia (LIP)                 |
| 516.36*                   | Cryptogenic organizing pneumonia (COP)                           |
| 516.37*                   | Desquamative interstitial pneumonia (DIP)                        |
| 516.8                     | Other specified alveolar and parietoalveolar pneumonopathies     |
| 516.9                     | Unspecified alveolar and parietoalveolar pneumonopathy           |
| 518.82†                   | Acute respiratory distress syndrome                              |

\* Additional five digit diagnosis codes were approved by the ESC on 12 March 2013

† Acute respiratory distress syndrome code was approved on 30 September 2013

---

## **APPENDIX 4. DOD DATABASE – QUARTERLY REPORTS OF PATIENT ACCRUALS**

---

**Table 1. Numbers of patients by drug cohort, with numbers screened according to each screening criteria (only initial cohort in retrospective period)**

| <b>Patients Identified Jul 2009 - Dec 2011 (Retrospective Period)</b>                      | <b>Dronedarone</b> | <b>Amiodarone</b> | <b>Sotalol</b> | <b>Flecainide</b> | <b>Dofetilide</b> | <b>Propafenone</b> | <b>Total</b>  |
|--------------------------------------------------------------------------------------------|--------------------|-------------------|----------------|-------------------|-------------------|--------------------|---------------|
| Patients with each study drug between 7/20/09 and 12/31/11*                                | 16,639             | 51,091            | 22,261         | 12,081            | 3,209             | 10,200             | 115,481       |
| 1st study drug from 7/20/2009**                                                            | 10,769             | 47,018            | 20,319         | 10,740            | 2,288             | 9,054              | 100,188       |
| <i>Less patients without 365 days of eligibility prior the 1st study drug (index date)</i> | <i>140</i>         | <i>480</i>        | <i>445</i>     | <i>401</i>        | <i>50</i>         | <i>210</i>         | <i>1,726</i>  |
| Remaining patients                                                                         | 10,629             | 46,538            | 19,874         | 10,339            | 2,238             | 8,844              | 98,462        |
| <i>Less patients without AF in the year prior to index date</i>                            | <i>1,466</i>       | <i>12,604</i>     | <i>4,850</i>   | <i>2,947</i>      | <i>234</i>        | <i>2,065</i>       | <i>24,166</i> |
| Remaining patients                                                                         | 9,163              | 33,934            | 15,024         | 7,392             | 2,004             | 6,779              | 74,296        |

1. This Table will be completed each quarter during the prospective count.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all serious liver injury cases will be captured regardless of whether the

\*Liver injury diagnoses reported on date of first liver injury diagnosis after index date, for patients exiting liver injury monitoring cohort in this period due to liver injury diagnosis.

Note: Rows are not mutually exclusive. Percentage is calculated as number of patients for the individual code divided by the Overall Surveillance Study Medication Cohort patient count.

1. This Table will be completed each quarter during the prospective count.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all serious liver injury cases will be captured regardless of whether the  
\*Lung disease diagnoses reported on date of first lung disease diagnosis after index date, for patients exiting lung disease monitoring cohort in this period due to lung disease diagnosis.

Note: Rows are not mutually exclusive. Percentage is calculated as number of patients for the individual code divided by the Overall Surveillance Study Medication Cohort patient count.

**Table 1. Number of Patients by Drug Cohort and Screening Criteria, US DoD Database: January to March 2012**

| Description                                                       | Dronedarone | Amiodarone   | Sotalol    | Flecainide | Dofetilide | Propafenone | Total        |
|-------------------------------------------------------------------|-------------|--------------|------------|------------|------------|-------------|--------------|
| Patients with a study drug between 1/1/2012 and 3/31/2012         | 7,363       | 20,146       | 12,687     | 7,082      | 2,011      | 5,261       | 53,653*      |
| Less patients already in previous surveillance dataset            | 4,469       | 6,515        | 3,424      | 2,009      | 736        | 1,335       | 18,148*      |

\* Rows are not mutually exclusive. Percentage is calculated as number of patients for the individual code divided by the number of patients with an outcome.

Next quarter we will capture the following codes:

- 516.30 Idiopathic interstitial pneumonia, not otherwise specified (IIP)
- 516.31 Idiopathic pulmonary fibrosis (IPF)
- 516.32 Idiopathic non-specific interstitial pneumonitis (NSIP)
- 516.33 Acute interstitial pneumonitis (AIP)
- 516.34 Respiratory bronchiolitis interstitial lung disease (RB-ILD)
- 516.35 Idiopathic lymphoid interstitial pneumonia (LIP)
- 516.36 Cryptogenic organizing pneumonia (COP)
- 516.37 Desquamative interstitial pneumonia (DIP)

Table 4. Age / Gender Demographics for by Drug Cohort, US DoD Database, July 1, 2009 to Sep 2012

| Age Group / Gender    | Dronedarone   |              | Amiodarone    |              | Sotalol      |              | Flecainide   |              | Dofetilide |              | Propafenone  |              | Total         |              |

\* Degge received a refreshed eligibility record file from Health ResearchTX that contained updated eligibility records from July 2009 through December 2012. Previously, only quarterly eligibility status by month was provided for each quarterly update; changes in eligibility status in previous quarters was not provided.

\* Rows are not mutually exclusive. Percentage is calculated as number of patients for the individual code divided by the number of patients with an outcome. Blue text indicates an additional code added.

Note: Patient counts reflect the only the first occurrence after the index date of a diagnosis code that defines ILD.

\* Rows are not mutually exclusive. Percentage is calculated as number of patients for the individual code divided by the number of patients with an outcome.

Note: Patient counts reflect the only first occurrence after the index date of a diagnosis code that defines ILD.

\* Rows are not mutually exclusive. Percentage is calculated as number of patients for the individual code divided by the number of patients with an outcome.

Note: Patient counts reflect the only first occurrence after the index date of a diagnosis code that defines ILD.

**Table 4. Age / Gender Demographic of Patients (with a Study Drug of Interest between 7/20/2009 and 03/31/2014) by Study Drug Cohort; US DoD Database (2014Q2)**

\* Rows are not mutually exclusive. Percentage is calculated as number of patients for the individual code divided by the number of patients with an outcome.

Note: Patient counts reflect the only the first occurrence after the index date of a diagnosis code that defines ILD.

**Table 4. Age / Gender Demographic of Patients (with a Study Drug of Interest between 7/20/2009 and 03/31/2014) by Study Drug Cohort; US DoD Database (2014Q3)**

| <div>1. This Table will be completed each quarter during the prospective count.</div> <div>2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all serious liver injury cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.</div> <div>3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.</div> <div>4. Percentages are reported as the number of patients identified with the listed code divided by the total number of patients identified as new index users in the cohort.</div> |                                                                          |                   |                |                   |                   |                    |              |              |                                                                                       |                                                                                                                                      |

| <div>1. This Table will be completed each quarter during the prospective count.</div> <div>2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all interstitial lung disease cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.</div> <div>3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.</div> <div>4. Percentages are reported as the number of patients identified with the listed code divided by the total number of patients identified as new index users in the cohort.</div> |                                                                          |                            |                         |                            |                          |                             |                        |  |                                                                                                            |                                                                                                                                                           |

1. This Table will be completed each quarter during the prospective count.

2. Only the index study drug will be counted, therefore a patient is only counted once.

3. Percentages are reported as the number of patients identified in the cohort and specified period divided by the total number of patients in the cohort.

4. Eligibility criteria were reassessed for patients identified during the retrospective period and only those still eligible are included.

1. This Table will be completed each quarter during the prospective count.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all serious liver injury cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Eligibility criteria were reassessed for patients identified during the retrospective period and only those still eligible are included.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

Table 3. Interstitial Lung Disease Counts, By Cohort, HealthCore Integrated Research Database (HIRD)<sup>1,2,3</sup>

1. This Table will be completed each quarter during the prospective count.
2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all interstitial lung disease cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.
3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.
4. Eligibility criteria were reassessed for patients identified during the retrospective period and only those still eligible are included.
5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.
6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

1. This Table will be completed each quarter during the prospective count.  
2. Only the index study drug will be counted, therefore a patient is only counted once.  
3. Eligibility criteria were reassessed for patients identified during the retrospective period and only those still eligible are included.

1. This Table will be completed each quarter during the prospective count.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all SLI cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

1. This Table will be completed each quarter during the prospective count.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all ILD cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

Table 4. Age Distribution of Index Users, By Gender and Cohort, Through End of Current Period (Jul 2009 - Jul 2012), HealthCore Integrated Research Database (HIRD)<sup>SM1,2,3</sup>

1. This Table will be completed each quarter during the prospective count.

2. Only the index study drug will be counted, therefore a patient is only counted once.

3. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

1. This Table will be completed each quarter during the prospective count.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all SLI cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

1. This Table will be completed each quarter during the prospective count.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all ILD cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

**Table 4. Age Distribution of Index Users, By Gender and Cohort, Through End of Current Period (Jul 2009 - Nov 2012), HealthCore Integrated Research Database (HIRD)** <sup>SM,1,2,3</sup>

1. This Table will be completed each quarter during the prospective count.

2. Only the index study drug will be counted, therefore a patient is only counted once.

3. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

1. This Table will be completed each quarter during the prospective count.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all SLI cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

1. This Table will be completed each quarter during the prospective count.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all ILD cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

1. This Table will be completed each quarter during the prospective count for fully insured patients only, for whom claims profiles can be shared externally outside of HealthCore, Inc.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all SLI cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

Table 3. Interstitial Lung Disease (ILD) Counts, By Cohort and Period, HealthCore Integrated Research Database (HIRD)<sup>SM,1,2,3</sup>

1. This Table will be completed each quarter during the prospective count for fully insured patients only, for whom claims profiles can be shared externally outside of HealthCore, Inc.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all ILD cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

| 1. This Table will be completed each quarter during the prospective count for fully insured patients only, for whom claims profiles can be shared externally outside of HealthCore, Inc.<br>2. Only the index study drug will be counted, therefore a patient is only counted once.<br>3. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included. |                                    |               |                                   |               |                                |               |                                   |               |                                 |              |                                    |              |                               |        |

# **Age Distribution of Index Users, By Cohort, Through End of Current Period (Jul 2009 - May 2013), HealthCore Integrated Research Database (HIRD<sup>SM</sup>)**

## Table of Contents

Table 1. New Index Dronedaronone and Comparator User Counts (Patient-Level), HealthCore Integrated Research Database<sup>SM</sup> (HIRD)

Table 2. Serious Liver Injury (SLI) Counts, By Cohort and Period, HealthCore Integrated Research Database<sup>SM</sup> (HIRD)

Table 3. Interstitial Lung Disease (ILD) Counts, By Cohort and Period, HealthCore Integrated Research Database<sup>SM</sup> (HIRD)

Table 4. Age Distribution of Index Users, By Gender and Cohort, Through End of Current Period (Jul 2009 - Nov 2013), HealthCore Integrated Research Database<sup>SM</sup> (HIRD)

Figure 1. Age Distribution of Index Users, By Cohort, Through End of Current Period (Jul 2009 - Nov 2013), HealthCore Integrated Research Database<sup>SM</sup> (HIRD)

| 1. This Table will be completed each quarter during the prospective count for fully insured patients only, for whom claims profiles can be shared externally outside of HealthCore, Inc.<br>2. Only the index study drug will be counted, therefore a patient is only counted once.<br>3. Percentages are reported as the number of patients identified in the cohort and specified period divided by the total number of patients in the cohort.<br>4. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included. |                    |               |                   |               |                |               |                   |               |                   |               |

1. This Table will be completed each quarter during the prospective count for fully insured patients only, for whom claims profiles can be shared externally outside of HealthCore, Inc.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all SLI cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

1. This Table will be completed each quarter during the prospective count for fully insured patients only, for whom claims profiles can be shared externally outside of HealthCore, Inc.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all ILD cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Eligibility criteria were reassessed for patients identified during the retrospective and prior prospective periods and only those still eligible are included.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

1. Among the HealthCore Integrated Research Database<sup>SM</sup> (HIRD) population including both fully insured and administrative services only (ASO) members, for whom claims profiles can now be shared externally outside of HealthCore, Inc.<sup>4</sup> The Epidemiology Study will be conducted using this patient population. Only the index study drug will be counted, therefore a patient is only counted once. Epidemiology Study Protocol patient identification and inclusion/exclusion criteria were assessed for all patients identified through the end of the current period. Percentages are reported as the number of patients identified divided by the number of patients with the first study drug assigned as the cohort.

2. Patients allowed to contribute to multiple index drug columns until excluding for multiple study drugs on index date. Blue-highlighted Total counts are unique patients and not the sum of counts across drug columns.

3. Additional screening to reflect Epidemiology Study Protocol.

4. Per study-specific exemption recently granted by HealthCore leadership in Oct 2014 to allow the inclusion of administrative services opt-in patients for this study. Such patients were excluded in all previous accrual reports.

1. Among the HealthCore Integrated Research Database<sup>SM</sup> (HIRD) population including both fully insured and administrative services only (ASO) members, for whom claims profiles can now be shared externally outside of HealthCore, Inc. Such patients were excluded in all previous accrual reports. The Epidemiology Study will be conducted using this patient population. For serious liver injury/disease (SLD) counts, patients with SLD in the baseline period were excluded.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all SLD cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Epidemiology Study Protocol patient identification and inclusion/exclusion criteria were assessed for all patients identified through the end of the current period.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

1. Among the HealthCore Integrated Research Database<sup>SM</sup> (HIRD) population including both fully insured and administrative services only (ASO) members, for whom claims profiles can now be shared externally outside of HealthCore, Inc. Such patients were excluded in all previous accrual reports. The Epidemiology Study will be conducted using this patient population. For interstitial lung disease (ILD) counts, patients with ILD in the baseline period were excluded.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all ILD cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Epidemiology Study Protocol patient identification and inclusion/exclusion criteria were assessed for all patients identified through the end of the current period.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

1. Among the HealthCore Integrated Research Database<sup>SM</sup> (HIRD) population including both fully insured and administrative services only (ASO) members, for whom claims profiles can now be shared externally outside of HealthCore, Inc. Such patients were excluded in all previous accrual reports. The Epidemiology Study will be conducted using this patient population.

2. Only the index study drug will be counted, therefore a patient is only counted once.

3. Epidemiology Study Protocol patient identification and inclusion/exclusion criteria were assessed for all patients identified through the end of the current period. Patients with serious liver injury/disease (SLD) or interstitial lung disease (ILD) in the baseline period were not excluded.

**Age Distribution of Index Users, By Cohort,  
Through End of Current Period (20 Jul 2009 - 31 Mar 2014),

| 1. Among the HealthCore Integrated Research Database <sup>SM</sup> (HIRD) population including both fully insured and administrative services only (ASO) members, for whom claims profiles can now be shared externally outside of HealthCore, Inc. <sup>4</sup> The Epidemiology Study will be conducted using this patient population. Only the index study drug will be counted, therefore a patient is only counted once. Epidemiology Study Protocol patient identification and inclusion/exclusion criteria were assessed for all patients identified through the end of the current period. Percentages are reported as the number of patients identified divided by the number of patients with the first study drug assigned as the cohort. |             |       |            |       |         |       |            |       |            |       |             |       |                    |       |
| 2. Patients allowed to contribute to multiple index drug columns until excluding for multiple study drugs on index date. Blue-highlighted Total counts are unique patients and not the sum of counts across drug columns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |       |            |       |         |       |            |       |            |       |             |       |                    |       |
| 3. Additional screening to reflect Epidemiology Study Protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |       |            |       |         |       |            |       |            |       |             |       |                    |       |
| 4. Per study-specific exemption recently granted by HealthCore leadership in Oct 2014 to allow the inclusion of administrative services opt-in patients for this study. Such patients were excluded in all previous accrual reports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |       |            |       |         |       |            |       |            |       |             |       |                    |       |

1. Among the HealthCore Integrated Research Database<sup>SM</sup> (HIRD) population including both fully insured and administrative services only (ASO) members, for whom claims profiles can now be shared externally outside of HealthCore, Inc. Such patients were excluded in all previous accrual reports. The Epidemiology Study will be conducted using this patient population. For serious liver injury/disease (SLD) counts, patients with SLD in the baseline period were excluded.
2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all SLD cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.
3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.
4. Epidemiology Study Protocol patient identification and inclusion/exclusion criteria were assessed for all patients identified through the end of the current period.
5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.
6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

1. Among the HealthCore Integrated Research Database<sup>SM</sup> (HIRD) population including both fully insured and administrative services only (ASO) members, for whom claims profiles can now be shared externally outside of HealthCore, Inc. Such patients were excluded in all previous accrual reports. The Epidemiology Study will be conducted using this patient population. For interstitial lung disease (ILD) counts, patients with ILD in the baseline period were excluded.

2. Since we are following patients from the index cohort until the end of the monitoring period, death, or disenrollment from their health plan, all ILD cases will be captured regardless of whether the patient stayed on the index drug or switched to another drug.

3. Counts by code are not mutually exclusive; a patient can be counted in multiple rows if the patient had multiple codes on the event date.

4. Epidemiology Study Protocol patient identification and inclusion/exclusion criteria were assessed for all patients identified through the end of the current period.

5. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of patients identified in the cohort and specified period.

6. Percentages are reported as the number of events identified in the cohort and specified period divided by the total number of events identified in the cohort and specified period.

1. Among the HealthCore Integrated Research Database<sup>SM</sup> (HIRD) population including both fully insured and administrative services only (ASO) members, for whom claims profiles can now be shared externally outside of HealthCore, Inc. Such patients were excluded in all previous accrual reports. The Epidemiology Study will be conducted using this patient population.

2. Only the index study drug will be counted, therefore a patient is only counted once.

3. Epidemiology Study Protocol patient identification and inclusion/exclusion criteria were assessed for all patients identified through the end of the current period. Patients with serious liver injury/disease (SLD) or interstitial lung disease (ILD) in the baseline period were not excluded.

**Age Distribution of Index Users, By Cohort,  
Through End of Current Period (20 Jul 2009 - 31 Mar 2014),  
HealthCore Integrated Research Database<sup>SM</sup> (HIRD)**

## PATIENT PROFILE LAYOUT

**Header information - this information lists the Patient ID, gender, age at index date, Index Date, and date of suspected outcome event.**

| Patient ID #      | Age:                               | Gender:        | Index Date:              | Event Date:                                                        | Date of Death: |
|-------------------|------------------------------------|----------------|--------------------------|--------------------------------------------------------------------|----------------|
| De-identified ID# | Patient's age as of the Index Date | Male or Female | Date of Index Study Drug | First occurrence after the index date of a suspected outcome event | Date of Death  |

**Patient's Medical History - medical/pharmacy encounter data is laid out in chronological order by the services rendered, oldest records appearing at the beginning and recent records at the bottom.**

| Line # | Time from Index | Date of Service/ Admit Date | Discharge Date | Code Type | Code | POS | Provider Specialty | Seq # | Code Description | Medication Name | Days Supply | QTY | Drug Formulation | Source | Record # |
|--------|-----------------|-----------------------------|----------------|-----------|------|-----|--------------------|-------|------------------|-----------------|-------------|-----|------------------|--------|----------|
|--------|-----------------|-----------------------------|----------------|-----------|------|-----|--------------------|-------|------------------|-----------------|-------------|-----|------------------|--------|----------|

### Column definitions:

|                              |                                                                                                                                                                                                                                                                    |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Line #                       | Sequential line number beginning with "1"                                                                                                                                                                                                                          |
| Time from Index              | Displays the number of days prior to the index date (e.g., -180, 180 days prior to the index date); and the number of days after the index date (e.g., 240)                                                                                                        |
| Date of Service / Admit Date | Contains the date of service for medical and pharmacy transactions. For inpatient stays, this date is the admission date.                                                                                                                                          |
| Discharge Date               | For code type=DX, PX, and CPT this date is the inpatient discharge date for inpatient stays.                                                                                                                                                                       |
| Code Type                    | Identifies the type of service transaction: <b>DX</b> = ICD-9-CM diagnosis code; <b>PX</b> = ICD-9-CM procedure code, CPT code, or HCPCS code; <b>RX</b> = Medication                                                                                              |
| Code                         | Actual code value reported for that transaction. For example, ICD-9-CM diagnosis/procedure codes, CPT codes, National Drug Codes (NDC)                                                                                                                             |
| POS                          | Place of Treatment (Services): Inpt (Hospital inpatient) indicates services that were performed at an inpatient hospital setting.                                                                                                                                  |
| Provider Specialty           | See Provider Specialty Codes Tabs for definitions                                                                                                                                                                                                                  |
| Seq #                        | The order in which the <b>diagnosis codes</b> appear on the claim/record form. 1=Primary, 2= secondary, etc...                                                                                                                                                     |
| Code Description             | Corresponding description of the code.                                                                                                                                                                                                                             |
| Medication Name              | Name of the medication dispensed                                                                                                                                                                                                                                   |
| Days Supply                  | For RX records, this value is the Days Supply.                                                                                                                                                                                                                     |
| QTY                          | For RX records, this value is the quantity dispensed.                                                                                                                                                                                                              |
| Drug Formulation             | For RX records, this is the drug formulation.                                                                                                                                                                                                                      |
| Source                       | This is the source of the transaction. <b>CAPER</b> =Direct Care-ProfessionalServices; <b>SIDR</b> =Direct Care-Inpt Records; <b>TEDN</b> =Purchased Care-Professional Services; <b>TEDI</b> =Purchased Care-Inpt Records; <b>PDTS</b> =Pharmacy Data Transactions |
| Record #                     | This number identifies the services/encounters associated with a transaction. There may be more than one transaction on a single day.                                                                                                                              |

### Color Coding

|                  |                                                                |
|------------------|----------------------------------------------------------------|
| Yellow highlight | Index study drugs are highlighted in yellow.                   |
| Orange highlight | Non-index study drugs are highlighted in orange.               |
| Olive highlight  | Skilled nursing facility stays are highlighted in olive green. |

Hospitalizations (admit to discharge) are highlighted in gray.

**Hospital Facility Records containing discharge diagnoses/procedures are in bold black text.**

**Hospitalized outcome events of interest are in bold red text.**

Non-hospitalized outcome events will be in plain red text.

Patient ID: SLD-0050

Age: 80 Gender: F Indexdate: 12/07/2009 Event Date: 01/26/2010 Date of Death: 02/03/2010
